PREFACE

In recent years, there has been tremendous growth in the number and types of laboratory data that can be obtained in the in-house veterinary practice laboratory. Laboratory procedures remain an important aspect of most veterinary practices, both diagnostically and financially, and a major responsibility of the technician. Performing the tests in the in-house veterinary practice laboratory also provides improved service to both the patient and client and an additional revenue source for the clinic.

This edition is an effort to collect the relevant clinical laboratory information needed by the practicing veterinary technician. Veterinary assistant and veterinary technology students will also find this a valuable everyday reference. Principles and procedures for laboratory diagnostics in clinical chemistry, microbiology, hematology, hemostasis, parasitology, urinalysis, immunology, and cytology are all presented. Information on commonly performed tests done in referral laboratories is also described to allow greater understanding of the clinical relevance of these tests. Reviews of anatomy and physiology topics are included in many sections to aid in developing an understanding of the rationale for performance of specific tests.

This new edition has been significantly updated with information on new technology and expanded information that reflects the latest developments in the veterinary clinical laboratory. Technician tips are interspersed throughout the text to highlight important points. Additional full-color illustrations have been added, including photomicrographs of blood cells, cytology, and microbiology samples, and urine sediment. Expanded information on new clinical analyzers is also included. Key points and recommended readings are included in each chapter.

Step-by-step procedure boxes for all commonly performed hematology, cytology, and parasitology laboratory tests are included in this new edition. The procedure boxes represent those skills that veterinary technician students must perform during their educational program, as well as additional procedures that are commonly performed by veterinary technicians in private veterinary practice.

ACKNOWLEDGMENTS

This volume would not have been possible without the hard work of all the contributors to the first six editions. I sincerely thank them for their efforts. I am grateful to the editors of the earlier additions, especially Teri Merchant, now retired from Elsevier and greatly missed, and Shelly Stringer, who effortlessly filled Teri's very large shoes. Brandi Graham, Maria Broeker, and Carol O'Connell have been invaluable in providing expert assistance in finalizing this new edition. I am grateful to Tim Baum and Katie Foust for their dedication to continuous improvement for this edition and the many veterinary technicians and veterinarians that provided assistance in obtaining many of the new illustrations in this edition.

To my friends, family, colleagues, current and former students, thank you all for your constant encouragement. You inspire me every day.

CONTENTS

Unit Outline

Chapter 1: Safety Concerns and OSHA Standards,
Chapter 2: General Laboratory Equipment,
Chapter 3: The Microscope,
Chapter 4: The Metric System and Lab Calculations,
Chapter 5: Quality Control and Record Keeping,

Unit Objectives

Describe the role of the veterinary technician in the clinical laboratory.
List and describe the regulations related to safety concerns in the veterinary practice laboratory.
Describe the components of a quality control program for the veterinary practice laboratory.
Identify, use, and maintain common laboratory equipment.
Use the metric system to perform calculations and measurements.

Veterinarians depend on laboratory results to help establish diagnoses, to track the course of diseases, and to offer prognoses to clients. The veterinary practice laboratory can also be a significant source of income for the practice. The rapid availability of test results improves patient care and client service. Although some veterinary clinics use outside reference laboratories for test results, this may delay the implementation of appropriate treat ments for patients. Most diagnostic tests can be performed in house by a well-educated veterinary technician. Veterinary practice laboratories have become increasingly sophisticated. Analytic instruments are affordable and readily available for inclusion in even the smallest veterinary clinic.

The veterinary technician/veterinarian team approach works efficiently in a laboratory situation. A veterinar ian is educated in the interpretation of test results, whereas a veterinary technician is educated on generating accurate test results. The consistent generation of reliable laboratory results requires an educated veterinary technician. A veterinary technician must understand the value of quality control in the laboratory.

The clinical laboratory should be separate from the main traffic flow in the clinic.

The laboratory area needs source of running water to provide place to rinse, drain, or specimens reagents to discard In every veterinary practice, caution be paramount; handling disposing of hazardous laboratory materials bear legal ethical responsibilities have increased substantially recent decades. Certain laboratory practices are essential for the protection of workers and the environment. Some of practices are simply good laboratory hygiene, whereas federal, state, local regulations have mandated others. thorough understanding of laws foundation of proper laboratory practices involve hazardous chemicals specimens. When doubt, veterinary tech never dispose of unknown reagents or chemicals down any drain.

Adequate storage space must be available for reagents sup to avoid clutter on laboratory counter space. Drawers cabinets be available needed supplies equipment are conveniently located site where they will be used. Some reagents specimens must be kept refrigerated or frozen. refrigerator freezer be readily available. compact countertop refrigerator sufficient for practice laboratories. Frost-free freezers remove from frozen thus them more concentrated they are left freezer too long. For long-term storage of (e.g., serum, chest freezer or freezer self-defrosting be used.

The placement of electrical equipment requires careful consideration. Sufficient electrical outlets circuit breakers must be available. Circuits must be overloaded with ungrounded three-prong adapters or extension cords. Veterinary technicians avoid working with around electrical wires or instruments. An uninterruptible power supply may be necessary sensitive equipment will be used or practice located an area that is subject to frequent power outages or fluctuations.

The diagnostic laboratory of progressive veterinary clinic have Internet access laboratory or another location within veterinary clinic. Many reference laboratories or to report critical results of submitted diagnostic tests. In veterinary clinic access to digital camera attachment for compound microscope, veterinarian veterinary technician Internet diagnostic Photographic images such scanned microscopic images of blood smears urine sediments may be sent attachments to outside reference laboratory for diagnostic assistance.

A computer with Internet access is a vital component

The Internet may be valuable resource for veterinary medical information. However, information on Internet may be oversimplified, incomplete, or inaccurate. The veterinary tech Internet sources for supplemental information in addition to consultation with the veterinarian. The veterinarian technician carefully examine all Internet resources together to determine quality of each website.

Two determinants are used to website quality. First, high-quality Internet sites are unbiased: group providing information have vested interest (e.g., selling product) slanting information certain way. Second, sources be staffed by recognized experts field, such

General Laboratory Equipment

After studying this chapter, you will be able to:

- List ypes quipment ommonly veterinary practice laboratory.
- Differentiate etween rizontal- led-head centrifuges.
- Describe roper entrifuge.
- Discuss lection roper ettes.
- Define erm efractive ex and describe the proper use of a refractometer.

Centrifuge
Incubator
Pipette
Refractive index
Refractometer
Supernatant

A variety of general laboratory equipment is needed for the in-house clinical laboratory. The size of the veterinary practice and the tests that are routinely performed in the laboratory determine the equipment and instrumentation needed. Minimal equip ment includes a microscope, a refractometer, a microhematocrit centrifuge, and a clinical centrifuge. Additional instrumentation that may be needed—including blood chemistry analyzers, cell counters, water baths, and incubators—depends on the type and size of the practice, the geographic locale of the practice, and the special interests of practice personnel. Test tubes, pipettes, heat blocks, and aliquot mixers are also commonly found in veterinary practices. The proper use and maintenance of this equipment are essential to ensure accurate test results and safety of personnel.

Test tubes that are used in the veterinary practice laboratory may be made of glass or plastic, and they are available in many sizes. Microhematocrit tubes, which are primarily used for evaluation of packed cell volume, may be plain or contain anticoagulant. Blood collection tubes are generally made of glass, and have color-coded caps to indicate whether any additives are present Fig. 2.1). Conical tubes have a narrow base and are most often used to centrifuge substances such as urine, which contain solid material within the solution (Fig. 2.2). Blood collection and conical tubes are available in a large number of sizes.

Centrifuges are vital instruments with many uses in the veterinary practice laboratory. The centrifuge is used to separate substances of different densities that are in a solution. The centrifuge spins samples at high speeds, which pushes the most dense components in the sample to the bottom of the tube. Liquid components are layered above the solid components, also according to their densities. When solid and liquid components are present in the sample, the liquid portion is referred to as the **supernatant** and the solid component is referred to as the sediment. The supernatant (e.g., plasma or serum from a blood sample) can be removed from the sediment and stored, shipped, or analyzed. Centrifuges vary in size, capacity (i.e., the number of tubes that can be spun at one time), and speed capabilities. Veterinary

Blood collection tubes are available in a variety of sizes and

Swinging-arm or horizontal-head centrifuge.

Conical Centrifuge Tube. This type of tube is used to centrifuge substances that contain solid material in solution.

cally designed for small sample volumes.

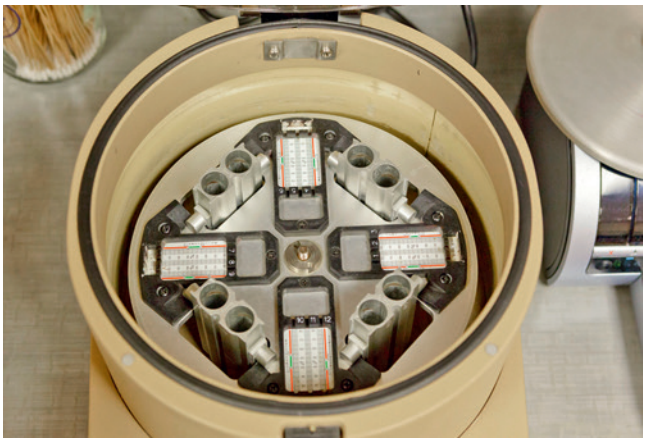
practice laboratories often have more than one type of centrifuge. A microhematocrit centrifuge is designed to hold capillary tubes, whereas a clinical centrifuge accommodates test tubes of varying sizes. Larger referral practices and reference laboratories may have additional types of centrifuges. A refrigerated centrifuge is used when materials must be kept cool during centrifugation (e.g., processing of blood components for transfusion therapy).

Centrifuges separate substances according to their

Clinical centrifuges that are used in veterinary laboratories are one of two types, depending on the style of the centrifuge head. A horizontal centrifuge head, which is also known as the "swinging-arm" type, has specimen cups that hang vertically when entrifuge uring entrifugation, the cups swing out to the horizontal position. As the specimen is centrifuged, centrifugal force drives the particles through the liquid to the bottom of the tube. When the centrifuge stops, the specimen cups fall back to the vertical position.

The horizontal head centrifuge has two disadvantages. At excessive speeds (i.e., greater than 300 revolutions/min), air friction causes heat buildup, which can damage delicate specimens. In addition, some remixing of the sediment with the supernatant may occur when the specimen cups fall back to the vertical position when the centrifuge head stops spinning.

The second type of centrifuge head that is available is the angled centrifuge head. The specimen tubes are inserted through drilled hold tubes fixed angle, usually of approximately 52 degrees. This type of centrifuge rotates at higher speeds than the horizontal-head centrifuge, without excessive heat buildup. The led entrifuge ually onfigured ccommodate just one tube size. Smaller-sized tubes require the use of an adapter unless a small-capacity centrifuge is available (Fig. 2.4). Microhematocrit centrifuges are a type of angled centrifuge. The microhematocrit centrifuge configured to accommodate lary tubes. In veterinary practice, the microhematocrit centrifuge is used for evaluation of the packed cell volume in a whole blood sample. Centrifuges that combine the features of more than one type of centrifuge are also available (Fig. 2.5



centrifuge is used to spin microhematocrit tubes.

In addition to a standard on/off switch, most centrifuges have a timer that automatically turns the centrifuge off after a preset time. A tachometer or dial to set the speed of the centrifuge is also usually present. Some centrifuges do not have a tachometer and always run at maximal speed. Most centrifuges have speed dials that have been calibrated in revolutions per minute (rpm) times 1000. Thus, a dial setting of 5 represents 5000 pm. Some laboratory procedures require specific relative centrifugal force (RCF) or G-force be used. The calculation of RCF requires measurement of the radius of the centrifuge head (r), measured from the center to the axis of rotation. The RCF is then calcu lated as follows:

118 10

A centrifuge may also have a braking device to rapidly stop it. The brake should only be used in cases of equipment malfunc tion, when the centrifuge must be stopped quickly. The centrifuge must never be operated with the lid unlatched. Always load the centrifuge with the open ends of the tubes toward the center

Verify that the load is properly balanced, with tubes of equal size and weight

of the centrifuge head. Tubes must be counterbalanced with tubes of equal size and weight placed directly opposite from each other. Water-filled ubes entrifuge. This ensures that the centrifuge will operate correctly without wobbling and that no liquid is forced from the tubes during operation. Incorrect loading of the centrifuge can cause damage to the instrument and injury to the operator. The centrifuge should be cleaned immediately if anything is spilled inside it. Tubes sometimes crack or break during centrifugation. Pieces of broken tubes must be removed when the centrifuge stops. If these are not removed, they could permanently damage the centrifuge. Box 2.1 contains general rules for centrifuge operation.

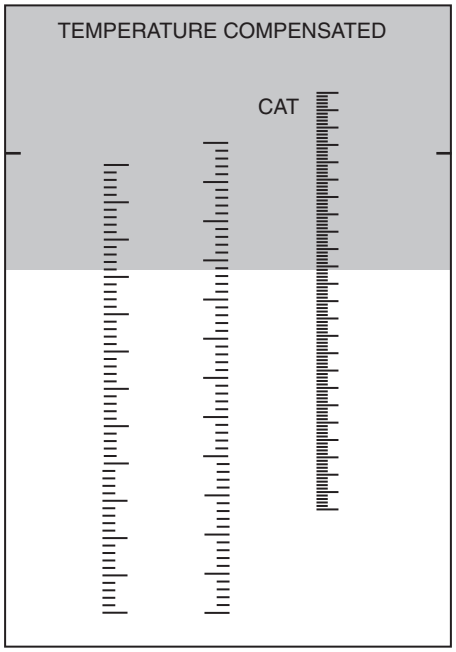
The operator's manual should list maintenance schedules for the different components of the centrifuge. Some centri fuges require periodic lubrication of the bearings, and most need the brushes to be checked or replaced regularly. Periodic verification entrifuge imer perating orrectly be performed with a stopwatch. Run the centrifuge at several speeds, and repeat each test run at least twice to ensure reproduc ibility. A tachometer can be used to verify that the centrifuge is reaching the appropriate speeds. A regular maintenance schedule prevents costly breakdowns and keeps the centrifuge running fficiency.

Centrifuges must always be balanced with tubes

Specimens must be centrifuged for specific time specific speed for maximal accuracy. A centrifuge that is run too fast or for too long may rupture cells or destroy the morphologic fea tures of cells in the sediment. A centrifuge may not completely separate the specimen or concentrate the sediment if it is run too slowly or for less than the proper time. Information about the speed and time of centrifugation should be developed for all laboratory procedures and strictly followed for maximal accuracy.

refractometer, or total solids meter, is used to measure the **refractive index** of a solution (Fig. 2.6). Refraction is the bending of light rays as they pass from one medium (e.g., air) into another medium (e.g., urine) that has a different optical density. The degree of refraction is a function of the concentration of solid material in the medium. Refractometers are calibrated to a zero reading (zero refractive index) with distilled water at a tempera ture of between 60° . The most common uses of the refractometer are for determination of specific gravity of urine or other fluids and the protein concentration of plasma and other fluids.

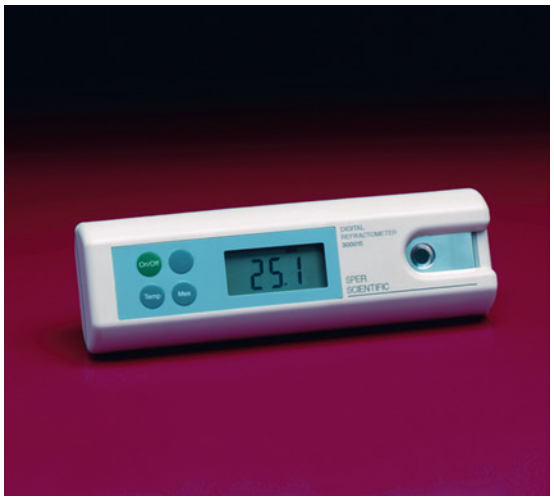
of urine specific gravity and total solids in plasma.



interface. (Courtesy B. Mitzner, DVM.)

The refractometer has a built-in prism and calibration scale Fig. 2.7). Although refractometers can measure the refractive index of any solution, the scale readings in the instrument have been calibrated terms of specific gravity ratio protein concentrations The specific gravity or protein concentration of a solution is directly proportional to its concentration of dissolved substances. Because no solution can be more dilute or have a lower concentration of dissolved substances than distilled water, calibration readings (either specific gravity or protein concentration) are always greater than zero. The refractometer is read on the scale at the distinct light–dark interface.

Various refractometer models are available. Most are temperature compensated between 60° . As long as the temperature remains between these two extremes, even as the refractometer is held in the hands, the temperature fluctuation will not affect the accuracy of the reading. Refractometers are available that are calibrated for canine, feline, and equine samples. The refractive index of some species correlates to a unique urine specific ravity eterinary-specific efractometers calibrated to account for those differences. Newer refractometers



Digital refractometer. (Courtesy B. Mitzner, DVM.)

are digital and contain a microprocessor that provides automatic calibration and temperature monitoring (Fig. 2.8

The procedure for the use of the refractometer is given in Procedure 2.1. The refractometer should be cleaned after each use and the prism cover glass and the cover plate wiped dry. Lens tissue should be used to protect the optical surfaces from scratches. Some manufacturers suggest cleaning the cover glass and plate with alcohol. The manufacturer's cleaning instructions should be consulted.

The refractometer should be calibrated regularly (i.e., weekly or y, epending istilled er oom empera ture placed on the refractometer should have a zero refractive index efore ead ecific ravity the light–dark boundary deviates from the zero mark by more than one-half of a division, the refractometer is adjusted by turning the adjusting screw as directed by the manufacturer. The refractometer should not be used if it is not calibrated to zero with distilled water.

Although most test kits and analyzers contain their own spe

pipettes and pipetting devices, some additional pipettes and pipetting devices may be needed in the veterinary practice laboratory. The primary types of pipettes used in the practice laboratory are transfer pipettes and graduated pipettes. Transfer pipettes are used when critical volume measurements are not needed. These pipettes may be plastic or glass, and some can deliver volumes by drops. Graduated pipettes may contain a single volume designation or have multiple gradations. Pipettes with single gradations are referred to as volumetric pipettes and are the most accurate of the measuring pipettes. It is important that the pipette be used correctly to ensure that the desired volume is measured. Always hold the pipette vertically, not tipped to the

side. er olumetric ettes ually esignated pipettes, which means that the pipette is designed "to deliver" the specific volume. small of liquid remain tip of the pipette after the volume has been delivered. Volumetric pipettes that have been designed to deliver microliter volumes are designated as TC pipettes, which means that the pipette is designed to contain" specified volume. These pipettes must only e d ecified olumes ubstances liquids. The pipette then must be rinsed with the other liquid to eliver ecified olume ccurately. olume fluid left in the tip of the pipette is then blown out of the pipette. Pipettes that contain multiple gradations are marked as either "TD" r TD low t," epending hether remaining in the tip of the pipette should remain or be blown out. with blow out pipettes usually contain double-etched or frosted band at the top.

Small incubator for use in the veterinary practice laboratory.

The ette hosen or ecific plication ways be the one that is the most accurate and that measures volumes closest to the volume needed. For example, if 0.8 eded, a 1-mL pipette rather than a 5-mL pipette should be chosen. Pipettes are designed for measuring liquids specified tem peratures, most commonly room-temperature liquids. Liquids that are nificantly older mer ill ure ccurately. Pipetting devices must also be used correctly, and fluid must not be allowed to enter the pipetting device. The pipette must be held vertically without tilting to the side when transferring liquids. Never pipette any fluid by placing your mouth directly on the pipette.

A variety of microbiology tests require the use of an **incubator** Incubators for the in-house veterinary practice laboratory are available ariety onfigurations. tor must be capable of sustaining a constant 37° which is the temperature at which the majority of pathogenic organisms grow. The incubator be fitted with thermometer, or one should be placed inside the chamber to monitor the tempera ture (Fig. 2.9). Heat should be provided by a thermostatically controlled element. A small dish of water should also be placed inside to maintain proper humidity. Some incubators have built-in humidity controls, but this type of equipment tends to be expensive. Larger laboratories may have incubators that auto matically monitor temperature and humidity as well as carbon dioxide and oxygen levels.

Many reagents and test kits that are used in the in-house vet erinary clinical laboratory require refrigeration, and some may

Aliquot mixer.

require storage in the freezer. Samples such as blood and urine may also require refrigeration. A basic tabletop refrigerator can be used for most items. This refrigerator may not contain any food for human consumption. Facilities that perform blood-banking services or transfusions must also have a special blood-bank refrigerator.

Some clinical chemistry assays, coagulation tests, and blood-banking procedures may require the use of a water bath or heat block that is capable of maintaining a constant temperature of

A variety of types of water baths are available, includ ing simple standard water baths, circulating water baths, and waterless bead baths. A rack must be placed inside the standard and circulating types to hold materials in place. Bead baths do not require a rack and have little need for maintenance. Heat blocks are generally designed to accommodate just one tube size, although some have multiple adapters that can be used for a variety of tube sizes (Fig. 2.10

A large number of automated analyzers are available for use in the in-house veterinary practice laboratory. These include hematology, clinical chemistry, electrolyte, immunology, coagula tion, and urine analyzers. The units may run single tests, or they may be capable of running multiple tests on the same sample. Analyzers vary considerably in test principle, and each one has specific dvantages dvantages. etailed ormation about yzers vailable or ecific ypes esting provided in their respective chapters.

Slide dryers can be a useful addition to the busy veterinary practice laboratory. The dryer minimizes the time required to prepare uch lood ell liquot ers helpful by keeping items well mixed and ready for use (Fig. 2.11

Chapter 2 review questions are in Appendix A

- Clinical entrifuges repare or ysis.
- Periodic calibration of centrifuge needed to ensure it is reaching the required speeds.
- The efractometer or veral ypes be calibrated on a regular basis to ensure diagnostic-quality results.
- A variety of additional supplies equipment may be needed veterinary practice laboratory, depending on specific tests performed.
- Pipettes veral ypes, ch led what differently.
- Proper ette nsures ccurate urement ubstances.

After studying this chapter, you will be able to:

- List oscope.
- Describe tions oscope.
- Describe roper oarse djustment knobs.
- List eps oscope
- Discuss enance oscope.

Quality Control and Record Keeping

After studying this chapter, you will be able to:

- Describe omponents uality urance rogram.
- Differentiate etween ccuracy recision.
- Describe thods or erifying ccuracy results.

Accuracy
Controls
Hemolyzed
Icteric
Lipemic
Preanalytic variables
Precision
Quality assurance
Reliability
Standard operating procedures
Standards

The term **quality assurance** refers to procedures established to nsure esting erformed ompliance accepted standards processes results are properly documented. Unlike human medical laboratories, veterinary facili ties e ubject egulations equire uality urance programs. However, without comprehensive quality assurance program, ccuracy recision oratory esults be verified. comprehensive quality assurance program addresses l ects peration oratory. These aspects include qualifications of laboratory personnel; **standard operating procedures** for care of all supplies equipment; collection handling procedures; methods equency erformance uality ontrol assays; ecord-keeping rocedures.

Accuracy, recision, eliability erms equently used to describe quality control, they are standards for any quality ontrol rogram. **Accuracy** efers o w losely esults agree ith rue uantitative alue onstituent. **Preci sion** magnitude of random errors reproducibility of urements. **Reliability** ility thod accurate recise. actors ect ccuracy recision are test selection, test conditions, quality, technician skill, electrical urges, quipment enance.

The erm est lection efers rinciple method. any eterinary oratories ere adapted om oratory ddition, clinical nificance esults ary erent species. Regardless of test method used, care must be taken to follow analytic procedure exactly; any deviation seriously affect ccuracy esults. uality reatly ects uality esults. **lipemic icteric** r **hemolyzed** y equire ecial efore clinical analyzers. The collection of blood from properly fasted nimals sing ppropriate echniques nd quipment ill minimize ce rror.

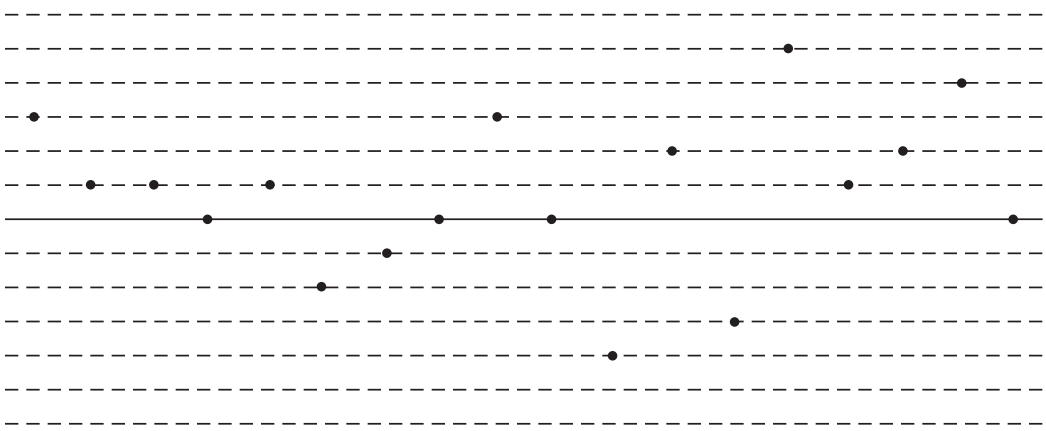
Individual laboratories may produce their own control serum. Serum obtained from clinically healthy of ne ecies ooled yzed umerous laboratory. ollected om istically analyzed o propriate anges alues.



The results of the analysis of a control serum are recorded on a chart or log for each assay.

procedure time-consuming, especially for smaller laboratories. For reason, purchasing of commercial control sera much more convenient.

Some manufacturers provide quality control service which test are sent to many laboratories for assay each month. The results from all of the laboratories are collected and compared. From results, manufacturer identify laboratories with accuracy problems.

Many factors other influence results of laboratory tests. These factors may be preanalytic, analytic, or postanalytic nature. Postanalytic factors are primarily related to entry record keeping.

Preanalytic variables may be biologic or nonbiologic. Biologic variables are factors are inherent to patient, such breed, age, gender. Because be controlled, they must be considered by veterinarian when test results are being evaluated. Other biologic variables involve factors be controlled when drawing blood such ensuring properly fasted. Nonbiologic variables are related to clerical errors well collection handling errors. Clerical errors are avoidable and include incor rect labeling, delays transporting incorrect tions, transcription errors, wrong patient. well-trained conscientious produces few clerical errors. Some of common problems related to handling are mislabeling incomplete or incorrect requisition forms. All tubes, slides, containers be labeled with owner's addition to patient's species, identification number available), date.

Analytic variables affect procedure by which analyte measured by instrument. The specific impact on test result will differ among laboratories, depending on type of instrumentation. Improperly maintained instruments errors are evident or trends results obtained with specific assay method. These errors often result gradual changes value of results to one direction to be elevated or decreased). Some factors systematic errors include inaccurate standard sera, reagent instability, method nonspecificity test method unsuitable for constituent being assayed).

Random errors are caused by variations found glassware pipettes, electronic optic variations of instruments, variations temperature controls timing. These errors occur all parts of system increase variability of results.

Instrument maintenance required to prolong life of instrument to prevent expensive downtime. All instruments are accompanied by an owner's manual. If the manual has been misplaced, manufacturer be contacted for replace ment. The manual instrument components must be inspected attended to regularly. notebook schedule with the types of maintenance required for each instru ment facilitates instrument maintenance. page dedicated to each instrument includes following information:

- Instrument

Unit Outline

Chapter 6: Hematopoiesis,
Chapter 7: Sample Collection and Handling,
Chapter 8: Automated Analyzers,
Chapter 9: Hemoglobin, PCV, and Erythrocyte Indices,
Chapter 10: Evaluating the Blood Smear,
Chapter 11: Morphologic Abnormalities of Blood Cells,
Chapter 12: Additional Hematologic Tests,
Chapter 13: Hematopoietic Disorders and Classification of Anemia,

Unit Objectives

List and describe the hematology evaluations that are commonly performed in veterinary practice.
Describe the components of blood.
Describe the development of the formed elements in blood.
Describe the appearance of normal blood cells and platelets.
Describe the appearance of commonly seen abnormal blood cells.
List the tests that comprise the complete blood count.
List and describe the equipment needed to perform a complete blood count.
Discuss aspects of quality control related to hematology testing.

Hematology is the science involved with the study of blood cells and their formation. Hematology testing represents an important role of the veterinary technician: providing accurate and reliable clinical laboratory test results to the veterinarian. An understanding of the principles of the various hematology tests and the methods used to ensure the accuracy of results is vital. The recent focus on the economic health of the veterinary clinic has also provided an opportunity for veterinary technicians to perform additional diagnostic testing, to improve overall animal care, and to provide an additional source of revenue for the clinic.

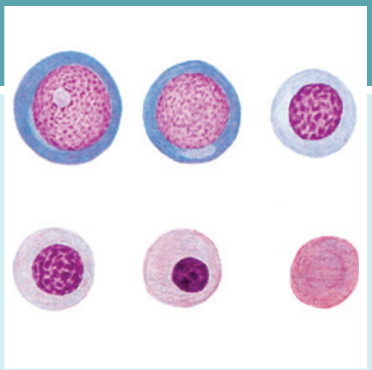
A complete hematology profile is indicated for the diagnostic evaluation of disease states, well-animal screening (e.g., geriatric), and as a screening tool before surgery. The complete blood count includes red and white blood cell counts, hemoglobin concentration, packed cell volume (PCV), a differential white blood film examination, and calculation of absolute values and erythrocyte indices. Additional tests that may be needed include reticulocyte counts, measurement of total solids, and thrombocyte (platelet) estimates. For some patients, additional information about the hematopoietic system is needed, and bone marrow evaluation must be per formed. Specific indications include unexplained nonregenerative anemia, leukopenia, thrombocytopenia, and pancytopenia (i.e., decreased numbers of all cell lines). Bone marrow evaluation is also used to confirm certain infections (e.g., ehrlichiosis) and to diagnose hematopoietic neoplasms (e.g., lymphoproliferative disorders).

Normal values, or reference ranges, for hematology results in common domestic animal species are located Appendix B. Please note that normal values are affected by a variety of factors, including the following:

- Testing thods
- Type f quipment
- Patient
- Patient ender
- Breed
- Reproductive

Laboratories should determine reference ranges for the tests performed in the clinic for the species that are commonly seen.

For dditional ces or esources ppendix extbook.



After studying this chapter, you will be able to:

- Define matopoiesis, ukopoiesis, rythropoiesis, thrombopoiesis.
- List rgans volved matopoiesis.
- Differentiate etween matopoiesis renatal dult
- Explain rythropoietin matopoiesis.
- List ells rythrocyte uration ries.
- List ells ukocyte uration ries.
- Describe ormation elets.

Chapter eview uestions ppendix

- Abnormalities are seen bone marrow be classified changes cell numbers or cell morphologic features maturation.
- Inflammatory conditions evident on examination of bone marrow aspirate are classified fibrinous, chronic, chronic granulomatous, or chronic pyogranulomatous.
- Neoplastic disorders of hematopoiesis are classified either lymphoproliferative or myeloproliferative.
- Anemia generally considered regenerative when per centage of reticulocytes peripheral blood equal to or greater expected percentage for corresponding PCV.
- Blood from patients with regenerative anemias may show evidence of increased macrocytosis, increased polychromasia, Howell-Jolly bodies.
- Common of nonregenerative anemia include iron deficiency, ehrlichiosis, drug toxicity, histoplasmosis, hypo thyroidism, renal insufficiency.
- Anemia can be classified as normocytic, macrocytic, or micro cytic addition to being normochromic or hypochromic.
- Anemia be classified by hemolytic or hemorrhagic, or may be result of decreased or defective production.

Unit Outline

Chapter 14: Principles of Blood Coagulation,
Chapter 15: Sample Collection and Handling,
Chapter 16: Platelet Evaluation,
Chapter 17: Coagulation Testing,
Chapter 18: Disorders of Hemostasis,

Unit Objectives

Describe the processes and pathways that lead to the clotting of blood.
List the components of the blood-clotting systems.
Describe the proper collection and handling of samples for coagulation testing.
Discuss the methods for the evaluation of platelets.
List and describe the coagulation tests commonly performed in the veterinary practice laboratory.
List and describe the coagulation tests commonly performed in the veterinary reference laboratory.
List and describe common inherited coagulopathies.
List and describe common acquired coagulopathies.

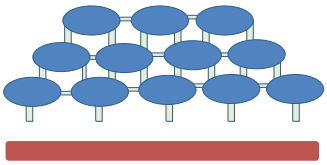
Hemostasis (i.e., blood clotting) involves multiple complex and interrelated processes. A variety of coagulation disorders can be seen in veterinary practice. A basic understanding of the processes involved in blood clotting is essential to ensure accurate test results.

A number of tests can be performed in the veterinary practice laboratory, and many of these tests do not require specialized equipment. Coagulation analyzers are also available for some tests and can be cost effective for the veterinary practice laboratory.

Normal values for blood coagulation tests are included in Appendix B

For additional sources for this unit see the Resources Appendix at the end of this textbook.

Principles of Blood Coagulation



After studying this chapter, you will be able to:

- Explain iew
- Describe ell-based del
- Explain elets iation oagulation.
- Describe on illebrand ctor lood coagulation.
- Discuss ormation oagulation omplexes.
- Describe ombin
- Discuss ormation rin egradation roducts D-dimers.

Overview of Blood Coagulation,
Coagulation Testing,

Review Questions,
Key Points,

Plasmin ct the insoluble fibrin to roduce oss-linked ersion **D-dimers** . lthough brief description given here seems complex, actual processes are great deal more complicated involve numerous dditional rum roteins. eader efer to ecommended eadings or re epth of mostasis. ummarizes iew chemical hase lood oagulation rocess.

Various coagulation tests have been developed to evaluate specific portions f mostatic chanisms. ome ure just chanical hereas rs measure pecific arts he hemical hase. ll atients hould be evaluated for coagulation defects before undergoing surgery. Most coagulation tests be completed with time equipment elatively xpensive.

Chapter eview uestions ppendix

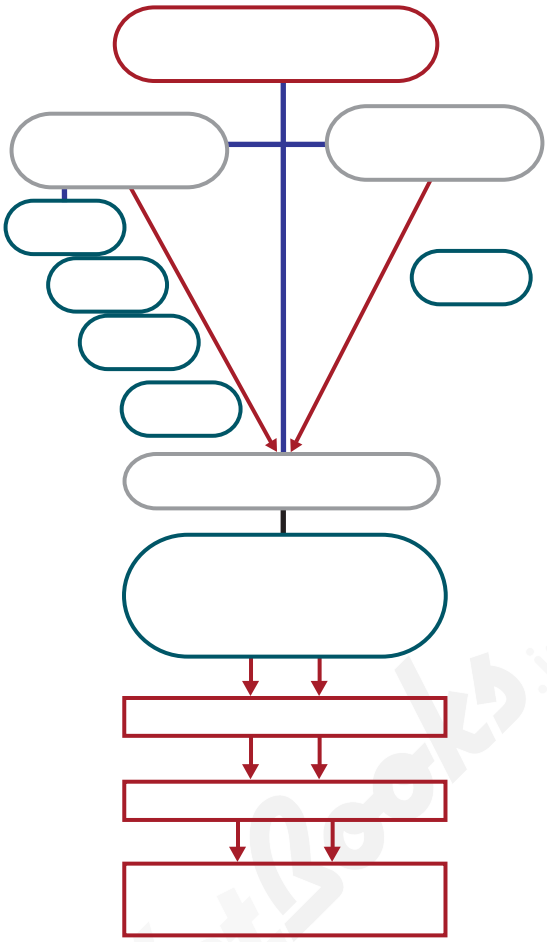

Fig. 14.4 A simplified summary of the chemical phase of hemostasis.

- Hemostasis requires platelets, number of coagulation factors, complex reaction pathways.
- Hemostasis proceeds through mechanical chemical pathways.
- The term mechanical hemostasis refers to aggregation adhesion of platelets to exposed blood vessel endothelium.
- The mechanical chemical phases of hemostasis are inter related interdependent.
- Activated platelets expose phosphatidylserine on their surface release microparticles contain phosphatidylserine.
- Coagulation complexes attach to phosphatidylserine on surfaces of microparticles platelets.
- Thrombin serves to enhance recruitment activation of platelets.
- Fibrinogen converted first to soluble form then to insoluble form.
- The breakdown of fibrin requires tPA.
- Fibrin broken down into soluble FDPs, insoluble FDPs, D-dimers.

Sample Collection and Handling

After studying this chapter, you will be able to:

- Describe roper ollection rocedures or coagulation esting.
- List icoagulants or lood oagulation tests.
- Describe thod etermine roper atio blood o rate icoagulant.
- Discuss roper or oagulation testing.
- Describe rumentation vailable or oagulation testing eterinary ractices eferral oratories.

Expected Laboratory Test Results for Common Bleeding Disorders

Activated clotting time; activated partial thromboplastin time; buccal mucosa bleeding time; fibrin degradation products;

Kirk & Bistner's handbook of veterinary procedures and emergency treatment

- Bleeding disorders may be caused by congenital or acquired defects coagulation proteins, platelets, or vasculature.
- Clinical signs of bleeding disorders include delayed deep-tissue hemorrhage, hematoma formation, superficial petechial and ecchymotic hemorrhages, epistaxis, melena, prolonged bleeding injection incision sites.
- The most common inherited coagulation disorder of domestic vWD.
- Thrombocytopenia refers to decreased number of platelets, common coagulation disorder seen small veterinary practice.
- Vitamin-K–dependent factors include Factors
- Thrombocytopenia be result of wide variety of conditions, including infection with certain bacterial, viral, parasitic agents. It may be caused by bone marrow depression or autoimmune
- DIC consumptive coagulopathy occurs secondary to other conditions.
- Clinical signs laboratory results are highly variable for patients with

Unit Outline

Chapter 19: Basic Principles of Immunity,
Chapter 20: Common Immunologic Laboratory Tests,
Chapter 21: Blood Groups and Immunity,
Chapter 22: Intradermal Testing,
Chapter 23: Reference Laboratory Immunoassays,
Chapter 24: Disorders of the Immune System,

The objectives for this unit are:

Describe the physiology of the immune system.
List the components of the immune system.
Describe the functions of the various immune system components.
Describe commonly performed tests that are used to evaluate the immune system.
Discuss disorders of the immune system.

The science of the detection and measurement of antibodies or antigens is called serology or immunology. Detection depends on the binding of antibodies and antigens. Unfortunately, this binding phenomenon is ordinarily invisible. Visualization—and thus detection—of the antigen–antibody reaction depends on sec ondary events by which the union is easily detected and therefore of diagnostic use in the veterinary practice.

The commercial production of monoclonal antibodies to many different antigens has resulted in a variety of test kits for use in the veterinary laboratory. These specific antibodies to many different antigens can be produced and used in the laboratory for the rapid identification of disease-producing organisms.

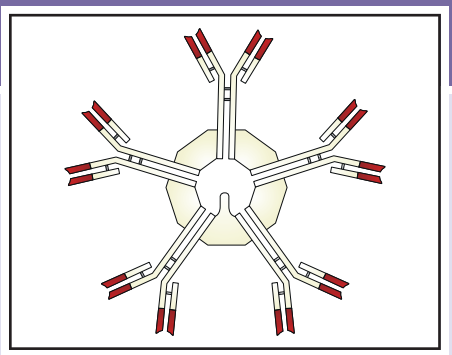
Immunization with viruses, bacteria, or other entities stimulates antibody production in an animal. The antibody-secreting, transformed lymphocytes (plasma cells) may be isolated from the animal and chemically fused with a type of "immortal" cell that propagates indefinitely, such as mouse myeloma cells. The antibodies that these hybrid cells produce, which are called monoclonal antibodies, are collected. Because each monoclonal antibody attaches to only one specific part of one type of molecule (antigen), the use of these antibodies in diagnostic kits makes the tests specific and greatly reduces interpretation problems of the results. For example, the feline leukemia virus antigen only reacts with the feline leukemia virus antibody. A specific reaction is diagnostically significant for this complicated disease. In addition to their specificity, these procedures allow for the rapid identification of the pathogen.

Many serologic tests involve the use of monoclonal antibodies. Enzyme immunoassay, latex agglutination, immunodiffusion, and rapid immunomigration are methods that are used in veterinary laboratories. Methods such as complement fixation, immunofluorescence, immunoelectron microscopy, virus neutralization, and polymerase chain reaction DNA amplification are used in veterinary reference laboratories and research facilities.

Reference laboratories offer myriad serologic tests specifically developed for veterinary samples. Tests for blood typing, allergies, bovine leukemia virus, reproductive hormones, Lyme disease, and brucellosis just are a few of the diagnostic tests currently available.

For additional sources for this unit see the Resources Appendix at the end of this textbook.

Basic Principles of Immunity



After studying this chapter, you will be able to:

- Differentiate etween stem adaptive stem.
- Describe omponents stem.
- Describe quence vents omprise system ory esponse.

Unit Outline

Chapter 25: Anatomy and Physiology of the Urinary System,
Chapter 26: Sample Collection and Handling,
Chapter 27: Physical Examination of Urine,
Chapter 28: Chemical Evaluation,
Chapter 29: Urine Sediment Analysis,

The objectives for this unit are:

Describe the formation of urine.
List and describe a variety of urine sample collection methods.
List and describe physical and chemical evaluations performed with urine samples.
Describe the formed elements that may be encountered in urine samples.
Describe the procedure for preparing urine for microscopic examination.
Describe the procedure for evaluating the formed elements in a urine sample.

Urinalysis is a relatively simple, rapid, and inexpensive laboratory procedure. It evaluates the physical and chemical properties of urine as well as the urine sediment. A urinalysis provides information to the veterinarian about the status of the urinary system, the metabolic and endocrine systems, and the electrolyte and hydration status. Therefore, the veterinarian may request that the owner bring a urine sample for initial testing. Samples may also be collected in-house using a variety of techniques.

Abnormalities in the urine may reflect a variety of disease processes involving several different organs. The basic equipment needed to perform a urinalysis is minimal and readily available in most veterinary clinics.

Quality assurance begins with proper specimen identification and handling. All samples should be labeled immediately after collection, and urinalysis should be performed as soon as possible. Reagent strips and tablets must be kept in tightly sealed bottles, and outdated reagents must be replaced with fresh reagents. Reactions for most constituents in the urine may be checked against available controls (e.g., Chek-Stix, Bayer Corpora tion, Leverkusen, Germany; Uritrol, YD Diagnostics, Seoul, Korea; Liquid Urine Control, Kenlor Industries, Inc., Santa Ana, CA). In addition, urine samples with distinct reactions for certain constituents sometimes may be preserved and used as positive controls. The results obtained from control samples and made-up controls should be plotted to determine whether observer drift or reagent decomposition is occurring. The urinalysis laboratory report should include patient information, collection technique, date and time collected, method of preservation (if used), and complete urinalysis results, including the results of microscopic examination results. A standard protocol for reporting results must be followed. See Appendix F for an example. Precision and accuracy need to be maintained by the veterinary technician for the proper interpretation of results.

Appendix B contains reference ranges for urinalysis tests of common domestic species.

For additional sources for this unit see the Resources Appendix at the end of this textbook.

Anatomy and Physiology of

urine may interact with acid decrease of protein precipitated.

This test used to help confirm significant of protein urine. To determine significance, urine protein concentration be compared with of creatinine. The centrifuged to separate particulate matter (cells) from dissolved substances (protein), creatinine protein concentrations of supernatant are used. The ratio obtained by dividing the protein concentration by the creatinine concentration. The ratio affected by urine concentration volume therefore accurate assessment of urine protein patients with low specific gravity.

Urine Values for Common Domestic Species

The presence of protein urine **proteinuria** usually abnormal, primarily attributable to of urinary tract or possibly of genital system. Occasionally small of protein found urine of normal Transient proteinuria may result from temporary increase glomerular permeability allows excessive protein to enter filtrate. This condition caused by increased pressure glomerular capillaries, may be found with muscle exertion, emotional stress, or convulsions. Occasionally small of urine protein found after parturition, during first few days of life, during estrus.

Very dilute urine may yield false-negative result, because protein concentration may be below sensitivity of testing method. trace of protein very dilute may be clinically significant, because dilute urine often occurs when large volume of urine being produced, such patient with chronic renal failure. Trace protein very dilute indicates higher degree of proteinuria trace present normally concentrated

In proteinuria indicates of urinary tract, especially of kidneys. Both acute chronic renal lead to proteinuria. Acute nephritis characterized by marked proteinuria with white blood cells (WBCs) urine, whereas with chronic renal degree of proteinuria qualitatively However, with chronic renal urine output usually excessive with low specific gravity; therefore total protein excreted actually quite significant. The ratio of urine protein to creatinine used to determine degree of protein patient with chronic renal

Multiple myeloma, which cancer of cells, may produce large quantities of light chain proteins (Bence Jones proteins) may through glomerulus. In patients with myeloma, proteins may be passed in the urine because they have damaged glomerulus or because they are "light chains" freely through glomerulus. Because proteins do react with protein pads on reagent strips, sul fosalicylic acid method is necessary to detect and quantify them.

Mild proteinuria seen with passive congestion of kidneys, occurs with congestive heart failure or any other impediment of blood flow from kidneys. Proteinuria of renal origin may be caused by trauma, tumors, renal infarcts, or necrosis results from drugs chemicals such sulfonamides, lead, mercury, arsenic, ether.

Inflammation of urinary or genital tract may pro teinuria of postrenal origin. Proteinuria may be seen with traumatic catheterization or bladder expression.

The presence of glucose urine known glucosuria or glycos uria. Glucose filtered through glomerulus resorbed by the kidney tubules. The amount of glucose in the urine depends on blood glucose levels on rates of glomerular filtra tion tubular resorption. Glucosuria usually does occur normal blood glucose level exceeds renal threshold (approximately to for dogs). At concentration, tubular resorption keep with glomerular filtration of glucose, glucose into urine.

Glucosuria occurs patients with diabetes mellitus result of deficiency of insulin or inability of insulin to function. Insulin necessary to transport glucose into body cells, deficiency hyperglycemia spilling of glucose into urine. high-carbohydrate may lead to blood glucose levels exceed renal threshold thus glucosuria. Because of period of fasting recommended before urine glucose concentration determined. Fear, excitement, or restraint (especially often hyperglycemia glucosuria result of epinephrine release. Glucosuria often occurs after intravenous administration of contain glucose occasionally after general Rarely, glucosuria found with hyperthyroidism, Cushing's chronic liver rare condition called renal glucosuria may occur when blood glucose concentration normal range. Renal glucosuria caused by reduced resorption of glucose renal tubules. Glucosuria may occur some with chronic possibly result of altered proximal renal tubular function.

False-positive results for glucose may be seen after of various drugs, including ascorbic acid (vitamin morphine, salicylates (e.g., aspirin), cephalosporins, penicillin.

Clinitest Reagent Tablets for the detection of sugars in the urine.

Various eagent rips vailable etect lucose urine. Clinitest Reagent Tablets (Bayer Corporation, Leverkusen, Germany) Fig. are available. These tablets detect any sugar hereas eagent rips etect nly glucose.

Clinical Chemistry

Unit Outline

Chapter 30: Sample Collection and Handling,
Chapter 31: Automated Analyzers,
Chapter 32: Protein Assays and Hepatobiliary Function Tests,
Chapter 33: Kidney Function Tests,
Chapter 34: Pancreatic Function Tests,
Chapter 35: Electrolytes and Acid–Base Status,
Chapter 36: Miscellaneous Tests,

The objectives for this unit are:

List and describe the types of clinical chemistry analyzers available for the veterinary practice laboratory.
Describe proper sample collection and handling for clinical chemistry assays.
List the commonly performed clinical chemistry evaluations and the significance of abnormal test results.
Describe electrolyte and acid-base analyses and the significance of abnormal test results.

In both human and veterinary medical practice, current trends indicate a move toward greater point-of-care capabilities. This translates into better customer service, and it enhances the practice of veterinary medicine. Determinations of levels of the various chemical constituents in blood can be an important aid in the formu lation of an accurate diagnosis, the prescription of proper therapy, and the documentation of the response to treatment. The chemicals being assayed are generally associated with particular organ functions. They may be enzymes associated with particular organ functions or metabolites and metabolic by-products that are processed by certain organs. Analysis of these components usually requires a carefully collected blood serum sample. Plasma may be used in some cases.

Many veterinary practices own or lease chemistry analyzers to perform routine chemical assays. This focus on in-house laboratory work makes veterinary technicians' laboratory skills perhaps their biggest asset to the practice. As the person most likely to be in charge of the laboratory, the veterinary technician must become familiar with the types of analytic instruments available, the variety of testing procedures used, and the ratio nales underlying the analyses. The most important contribution that the technician can make to the practice laboratory is providing accurate and reliable test results. In vitro results must reflect, as closely as possible, the actual in vivo levels of blood constituents.

There are literally hundreds of biochemical tests that can be performed on serum samples. The average veterinary practice laboratory probably performs a few dozen of these. The more common ones are included in this unit. Additional tests that are commonly performed at veterinary reference laboratories are also discussed. Although the tests are categorized primarily by the organs involved, it should be noted that some tests may be affected by the function of more than one organ or system. For example, amylase has multiple organ sources, and protein levels can be affected by many factors, including liver and kidney damage, metabolic status, and dehydration.

For additional sources for this unit see the Resources Appendix at the end of this textbook.

law. This principle states direct relationship exists between concentration of analyte light absorption when monochromatic light light of single wavelength) passed through The law states transmis sion of monochromatic light through concen tration of analyte have inverse exponential relationship. The degree of color change proportional to solution's concentration.

Most photometric analysis procedures are **end point assays** In other words, reaction occurs between reagent reaches stable end. The analyzer then either one-point calibration or internal standard curve to calculate patient results. Either method requires of standard. standard nonbiologic solution of analyte, usually distilled water, with known concentration. For one-point calibration, standard analyzed concurrently manner patient reaction characteristics are

Diagnostics, Columbia, MD.)

mathematically compared with patient The specific type of calculation varies, depending on the analyzer. In general, however, ratio of optical density of reacted standard is compared with the OD of the patient sample. OD is logarithmic function describes degree to which light transmitted through medium. An example of type of calculation follows:

The internal standard curve created when analyzer calibrated. To perform standard curve, serial dilutions of standard solution are created, each analyzed to determine absorbance or transmittance of light. The results from each dilution are plotted on graph straight The concentra tions of subsequent patient are determined by locat intersection of absorbance of reacted patient with on graph. Analyzers standard curve methods must be recalibrated each time new reagent purchased.

Some analyzers kinetic methods rather end point methods. These are primarily used for enzyme assays or when reagent enzyme based. Enzymes induce chemical changes other substances (called substrates), but they are inher ently changed. An enzyme may increase rate of biochemical reaction by acting catalyst to reaction. Most enzymes are formed function intracellularly, they are found their highest concentrations within cells. For reason, blood level of enzymes low healthy The blood level of enzyme may be elevated enzyme leaked out of damaged cells or cells have increased production of enzyme excess leaked out of cells into blood. Each specific enzyme catalyzes reaction of one specific substrate. Each enzymatic reaction produces specific product from interaction of substrate enzyme. The reaction forms product, but there change enzyme. Because blood levels of enzymes are low, directly measuring enzyme concentrations The tests performed to deter enzyme concentrations blood indirectly measure enzyme concentration present by directly measuring rate of formation of product of enzymatic reaction

acids. The enzymes are therefore found tissues have high rates of protein catabolism. Although other trans are present hepatocytes, only readily available tests are for ALT AST. Dehydrogenases catalyze transfer of hydrogen groups, primarily during glycolysis. Transaminases dehydrogenases are found either free cytoplasm of hepatocytes or bound to cell membrane. The serum levels of enzymes vary different species, have nonhepatic sources.

The common enzyme tests of liver function that are

In dogs, primates, major source of ALT hepa tocyte, where enzyme found free cytoplasm. ALT considered liver-specific enzyme species. Horses, rumi pigs, birds do have enough ALT hepatocytes for enzyme to be considered liver specific. Other sources of ALT are renal cells, cardiac muscle, skeletal muscle, pancreas. Damage to tissues may result increased serum ALT levels. The administration of corticosteroids or anti convulsant medications may also lead to increases in serum ALT. ALT used screening test for liver because precise enough to identify specific liver No correlation exists between blood levels of enzyme severity of hepatic damage. Increases ALT are usually seen within hours of hepatocyte damage, peak levels are seen to hours. The serum levels will return to reference ranges within few weeks chronic liver insult present.

present hepatocytes, which are found free cyto well bound to mitochondrial membrane. More severe liver damage required to release membrane-bound AST. levels tend to rise more slowly do ALT levels, they return to normal levels within day provided chronic liver insult present. found significant many other tissues, including erythrocytes, cardiac muscle, skeletal muscle, kidneys, pancreas. An increased blood level of may indicate nonspecific liver damage, or may be caused by strenuous exercise or intramuscular injection. The common of increased blood levels of are hepatic muscle inflammation or necrosis, spontaneous or artifactual hemolysis. If level elevated, serum or be examined for hemolysis. Creatine activity be assessed to rule out muscle damage before attributing increase to liver damage.

The primary source of hepatocyte. Smaller of enzyme are found kidney, small intestine, skeletal muscle, erythrocytes. present hepatocytes of all common domestic species, but it is especially useful for evaluating liver damage large such sheep, goats, swine, horses,

Large hepatocytes do contain diagnostic levels of ALT, offers liver-specific diagnostic test. The level of rises quickly with hepatocellular damage or necrosis. assay be used all species to detect hepatocel lular damage or necrosis, thereby eliminating need for other tests (e.g., ALT assay). The disadvantage of analysis unstable serum, activity declines within few hours. If testing delayed, be frozen. tests are readily available to average veterinary laboratory. Samples to be sent to outside laboratories be packed ice for transport.

mitochondrial-bound enzyme found high con centrations hepatocytes of sheep, goats. An increase enzyme indicative of hepatocyte damage or necrosis sheep. could be enzyme of choice for evaluating ruminant avian liver function, but standardized test method been developed for veterinary practice laboratory.

Blood levels of certain enzymes become elevated with cholesta (bile duct obstruction), metabolic defects liver cells, administration of certain medications, result of action of certain hormones, especially of thyroid. These enzymes are primarily membrane bound. The exact mechanism induces increased levels of enzymes when cholestasis present well documented.

Alkaline phosphatase present isoenzymes many tissues, particularly osteoblasts bone, chondroblasts tilage, intestine, placenta, cells of hepatobiliary system liver. The isoenzymes of tend to remain circulation for approximately to days, with exception of intestinal isoenzyme, which circulates for just few hours. corticosteroid isoenzyme of been identified dogs with exposure to increased endogenous or exogenous glucocorticoids. Because occurs isoenzymes various tissues, source of isoenzyme or location of damaged tissue may be determined by electrophoresis other tests are performed commercial or research laboratories.

In young comes from osteoblasts chondroblasts result of active bone development. In older nearly all circulating comes from liver bone development stabilizes. The assays are used for practice laboratory determine total blood concentration. concentrations are often used to detect cholestasis adult dogs Because of wide fluctuations normal blood levels sheep, test useful for detecting cholestasis species.

The pancreas actually two organs—one exocrine other **endocrine** e ogether roma. xocrine portion, hich eferred eas, om prises reatest ortion rgan. ortion cretes nzyme-rich uice ontains nzymes cessary or digestion estine. ee rimary eatic enzymes are **trypsin** **amylase** These digestive enzymes are released into lumen of other organs through duct system. Trauma o eatic issue ften ciated eatic duct inflammation results backup of digestive enzymes into eripheral culation.

Photo om hristenson *Veterinary medical terminology* d Louis, aunders.

Interspersed within exocrine pancreatic tissue are arrange ments of cells histologic section, take on appear ance of "islands" of lighter-staining tissue. These are called islets of Langerhans. Four types of islet cells are present, but they be distinguished on of their morphologic characteristics. The four cell types are designated pancreatic polypeptide cells. The cells comprise of islet cells, they secrete somatostatin pancreatic polypeptide, respectively. -Cells comprise approxi mately of islet, they secrete **insulin** The remaining nearly of islet consists of -cells secrete **glucagon** somatostatin. The pancreas regenerative ability. When pancreatic islets are damaged or destroyed, pancreatic tissue becomes firm and nodular, with areas of hemorrhage and necrosis. These islets are longer able to function. Diseases of pancreas may result inflammation cellular damage leakage of digestive enzymes or insufficient production or secretion of enzymes.

The tests are commonly performed to evaluate acinar functions of pancreas include amylase Trypsin like immunoreactivity serum **pancreatic lipase immuno reactivity** are available tests for pancreatic function. In serum amylase activities have been shown to have limited clinical significance for diagnosis of creatitis. In experimentally induced pancreatitis serum amylase actually decreases. The serum activities of both enzymes are frequently normal with pancreatitis. Several immunoassays are available provide either quanti tative or semi-quantitative evaluation of specific of dogs to rapidly differentiate pancreatitis from other states.

The primary source of amylase pancreas, but amylase produced in the salivary glands and the small intestine. Increases serum amylase are nearly always caused by pancreatic especially when accompanied by increased levels. The rise blood amylase level always directly proportional to severity of pancreatitis. Serial determinations provide information.

Amylase functions to break down starches glycogen sugars, such maltose residual **glucose** Increased levels of amylase appear blood during acute pancreatitis, flare-ups of chronic pancreatitis, or obstruction of pancreatic ducts. Enteritis, intestinal obstruction, or intestinal perforation may result increased serum amylase from increased absorption of intestinal amylase into bloodstream. In addition, because amylase excreted by kidneys, decrease glomerular filtration rate for any reason lead to increased serum amylase. Serum amylase activity greater three times refer ence range usually suggests pancreatitis.

Two amylase test methods are available: saccharogenic method **amyloclastic** method. The saccharogenic method measures production of reducing sugars amylase catalyzes breakdown of starch. The amyloclastic method measures disappearance of starch broken down to reduce sugars through amylase activity. Calcium-binding anticoagulants (e.g., EDTA) be used, because amylase requires pres ence of calcium for activity. The presence of lipemia may reduce amylase activity. The saccharogenic method ideal for because may artificially elevate assay results. Normal feline amylase values be to times higher found human beings. Therefore, may have to be diluted tests designed for human are used.

The majority of serum derived from pancreas. The function of to break down long-chain fatty acids of Excess normally filtered through kidneys, levels tend to remain normal during early stages of pancreatic Gradual increases are seen progresses. With chronic progressive pancreatic disease, damaged pancreatic cells are replaced with connective tissue produce enzyme. As occurs, gradual decrease both amylase levels are seen.

Chemical test methods for determination of levels are usually based on the hydrolysis of an olive oil emulsion into fatty acids by present patient serum. The quantity of sodium hydroxide required to neutralize fatty acids directly proportional to activity Newer tests for are capable of detecting feline pancreatic by immunologic methods are available. These tests have been demonstrated to have high degree of sensitivity for diagnosis of pancreatitis dogs assay may be more sensitive for detection of creatitis compared with amylase assay. The degree of activity, like amylase activity, directly proportional to severity of pancreatitis. Determinations of blood amylase activities are usually requested time to evaluate pancreas.

Increased activity seen with renal hepatic dysfunction, although exact mechanisms for are unclear. Steroid administration is correlated with increased lipase activity, with concurrent change amylase activity.

The comparison of amylase activity peritoneal with serum may provide additional diagnostic information. of higher amylase activity peritoneal serum strongly suggests pancreatitis, provided intes tinal perforation first been ruled out.

Trypsin proteolytic enzyme digestion by catalyzing reaction breaks down proteins of ingested food. Trypsin activity more readily detectable feces blood. For reason, trypsin analyses are performed on fecal Trypsin normally found feces, absence abnormal. variety of fecal testing methods are available reference laboratory.

glucose tests, other tests are available include **fructosamine** -hydroxybutyrate, **glycosylated hemoglobin** Urinalysis, serum cholesterol, triglyceride tests provide informa tion about function of pancreas.

The regulation of blood glucose levels complex. Glucagon, thyroxine, growth hormone, epinephrine, glucocorticoids are all agents favor **hyperglycemia** They boost blood glucose levels by encouraging glycogenolysis, gluconeogenesis, lipolysis while discouraging glucose entry into cells. Insulin hypo glycemic hormone. By promoting glucose into target cells, triggers anabolism, which process converts glucose into other substances. This regulatory effect prevents blood glucose concentration from exceeding renal threshold spilling of glucose into urine.

The pancreatic islets respond directly to blood glucose concentrations, they release insulin (from cells) or glucagon (from cells) needed. Glucagon release directly stimulates insulin release. Epinephrine under direct sympathetic neural control; hyperglycemia one aspect of classic "fight or flight" state. The other hormones mentioned respond to hypothalamic/pituitary command. At any point time, of agents are acting to blood glucose concentration or down.

Because only insulin lowers blood glucose levels, aberrations of insulin action have obvious clinical effects. Hypo function (diabetes mellitus) or hyperfunction (hyperinsulinism) occur.

The blood glucose level used indicator of carbohydrate metabolism body, may be used measure of endocrine function of pancreas. The blood glucose level reflects net balance between glucose production (e.g., dietary intake, conversion from other carbohydrates) glucose utiliza tion, which involves expended energy conversion into other products. It may reflect balance between blood insulin glucagon levels. Glucose levels fluctuate significantly due to variety of factors, including nutritional status stress. An individual blood glucose measurement reflects level present time collected.

Glucose utilization depends on of insulin glucagon produced by pancreas. As insulin level increases, does rate of glucose thereby resulting decreased blood glucose levels. Glucagon acts stabilizer to prevent blood glucose levels from becoming too low. As insulin level decreases (e.g., with diabetes mellitus), does glucose thereby resulting increased blood glucose concentration.

Many tests are available for blood glucose. Some of react only with glucose, whereas others may quantitate all sugars blood. point kinetic assays are available. The kinetic enzymatic assays tend to be accurate precise. Samples must be taken from properly fasted Serum for glucose testing must be separated from erythrocytes immediately after blood collection. Glucose levels may drop per of left contact with erythrocytes room temperature. Even of serum separator tube may be adequate to prevent Mature erythrocytes glucose for energy, blood they may decrease glucose level enough to give false-normal results original had elevated glucose level. If originally had normal glucose level, erythrocytes may enough glucose to decrease level to below normal or to zero. If be removed immediately, anticoagulant of choice sodium fluoride to of blood. Sodium fluoride may be used glucose preservative with EDTA at 2.5 mg/mL of blood. Refrigeration slows glucose use by erythrocytes.

Glucose levels may drop 10% per hour if the sample

Glucose bind variety of structures, including proteins. Fruc tosamine represents the irreversible reaction of glucose bound to protein, particularly albumin. When glucose concentrations are persistently elevated blood, occurs patients with diabetes mellitus, increased binding of glucose to serum proteins occurs. The of increased fructosamine indicates per sistent hyperglycemia. Because half-life of albumin dogs to weeks, fructosamine provides indication of average serum glucose over period. Fructosamine levels respond more rapidly to alterations serum glucose does glycosylated hemoglobin. However, serum fructosamine may be artifactually reduced patients with hypoproteinemia.

Glycosylated hemoglobin referred to hemoglobin represents irreversible reaction of hemoglo bin bound to glucose. When hyperglycemia present, there increased binding of hemoglobin glucose thus increased glycosylated hemoglobin. The of increased glycosylated hemoglobin indicates persistent hyperglycemia. The test result reflection of average glucose concentration over life of erythrocyte, which to months dogs to months Therefore, indicates blood glucose concentration over longer period of time either fructos or single blood glucose measurement. more specific diagnostic indicator of diabetes mellitus more sensi tive monitoring control of diabetes. With older test methods, patients were anemic often had artifactually reduced levels of glycosylated hemoglobin. Newer test methods are immunoassays are subject to errors from reduced hemoglobin.

Ketone bodies be detected The ketone produced greatest abundance ketoacidotic patients -hydroxybutyrate. However, many tests for serum ketones only detect acetone. Tests for -hydroxybutyrate enzymatic,

colorimetric thods ecoming vailable or eterinary

which e ommon rimary landular (e.g., neoplasia, autoimmune idiopathic atrophy) comprises whereas pituitary (secondary thyroid omprises ypothyroid ogs. ood ortion, stillbirths, pecia, oiter etuses onates), rum concentrations, serum protein-bound iodine concentrations, pasture iodine analyses. Feeds be xamined or oitrogenic *Brassica* spp.) or for excess calcium, which decreases iodine take.

In-house thyroid testing is generally performed with

Baseline thyroxine concentrations are used diagnostically, but normal values vary dramatically. Immunologic tests are available for urement oncentrations. ome ugs insulin, rogens) oncentrations; rs glucocorticoids, iconvulsants, ithyroid ugs, enicillins, trimethoprim ulfamides, epam, ogens, ulfonylureas) may decrease concentrations. In addition, total (TT may be eased ypothyroid ogs esult resence of i-T ibodies. ecific etermination ctive form of thyroxine non–protein-bound or free more accurate proach yroid tion.

The thyroid-stimulating hormone response test used on small xcept **hyperthyroidism** rses, provides reliable diagnostic separation of patients with normal versus normal yroid tion ox xogenous challenge may sort out borderline separate real hypo thyroid patients from with other illness or drug-depressed thyroxine oncentrations, oint ns.

The test usually used to explore hypothyroidism. fter TSH injected, thyroid response (usually serum levels, which provide eliable ex) ollowed. serum level occurs normal Primarily exhausted or insensitive yroids espond xogenous ndeed, endogenous TSH concentrations are already high from inhibition. Therefore, serum level increased ith uitary rain wever, yroid glands remain responsive. Such lesions result too endog enous yrotropin. lthough rum vel is xpected n nimals ith ituitary esions, ays SH

challenge may be necessary before increased serum levels are seen. The extra TSH required to overcome chronic glandular atrophy, method comparable to "priming pump."

Glucocorticoids seem to inhibit both TSH secretion, euthyroidism with low serum levels only often accompa Cushing's or vigorous glucocorticoid therapy. For tunately, TSH ACTH response tests may be performed simultaneously. In such glands remain responsive to TSH, but absolute values of prechallenge postchal lenge serum are low or low resting with normal post-TSH values. Feline hyperthyroidism usually caused by functional thyroid adenomas. Oddly, with exogenous TSH challenge, or increase occurs serum level, primary hypothyroidism. This phenomenon suggests neoplasm either functions independently of trophic hormone or already manufacturing maximum capacity. lack of TSH responsiveness, appropriate clinical manifesta tions, high baseline concentrations all attest to feline hyperthyroidism.

In horses, iodine-deficiency hypothyroidism rare, because iodized usually offered freely or feeds. Overzealous iodine supplementation with kelp or vitamin mineral mixes provoke hypothyroidism goiter. The excessive of iodine inhibits thyroid function. The normal serum values horses are to which lower what found other species. Hypothyroidism be suspected only with serum concentrations of

Rare tumors of pars intermedia of pituitary, which compress anterior pituitary, may secondary hypothy roidism older horses. Because pituitary damage induces plethora of signs, the TSH response test may be especially helpful.

The thyrotropin-releasing hormone (TRH) response test used on small provides reliable diagnostic separation of patients with normal versus abnormal thyroid function. fraction of thyroxine bound to protein. levels are influenced by nonthyroidal or drugs total concentrations. Exogenous challenge may sort out borderline separate real hypothyroid hyperthyroid patients from those with other illness or drug-depressed thyroxine concentrations. The test usually used to explore hypo thyroidism when TSH available. Baseline serum TT concentrations are determined. Four hours after or 0.2 (total dose) of TRH are injected intravenously, thyroid response (serum TT levels) followed. An increase serum TT concentration of concentration of times compared with baseline concentrations occurs normal The evaluation of levels allows for clearer distinction between euthyroid hypothyroid dogs when TT results are equivocal. The response test may be used to diagnose mild to moderate feline hyperthyroidism. Baseline serum concentrations are determined. Approximately hours after of are injected intravenously, serum levels are determined. An increase of serum of compared with baseline concentra tions occurs hyperthyroid Increases of between are borderline, increases of more rule out hyperthyroidism.

TECHNICIAN NOTE is the fraction of thyroxine that is not bound

Hyperthyroidism common middle-age to United States Great Britain. Diagnosis may be based on resting thyroid hormone concentrations. The determination of both TT may help to distinguish nonthyroidal The combination of high value with low TT level indicative of nonthyroidal illness, whereas high concentration high-normal TT concentration indicate hyperthyroidism. However, some may require functional test to confirm or rule out

Thyroid suppression testing based on expected negative feedback regulation of TSH, which induced by high concentra tions of circulating thyroid hormone. Hyperthyroid have normal pituitary–thyroid regulation. As result, administration of exogenous must induce decrease endog enous feedback TSH regulation altered.

To perform the test, basal and determination is required. Seven doses of given orally every hours are admin istered home. Approximately to hours after seventh dose, blood obtained for determination. Cats with hyperthyroidism have serum concentrations of more or whereas nonhyperthyroid have lower values. Low posttest concentrations indicate invalid test result of failure of exogenous administration.

The diagnosis of acromegaly may be based on docu mentation of elevated growth hormone level. Serial determinations from three to five taken 10-minute intervals) are performed because affected dogs have constant levels of rather fluctuating concentra tions. In addition, affected dogs do respond to stimulation with GH-releasing hormone. This test requires intravenous administration of of GH-releasing hormone or of clonidine. In normal dogs, the posttest plasma GH level increases to posttest clonidine level increases to

The principal functions of gastrointestinal tract are assimilation of nutrients (via digestion absorption) excretion of waste products. Most nutrients are ingested form either too complex or insoluble for absorption. Within the GI tract, these substances are solubilized and degraded enzymatically to molecules may be absorbed across mucosal epithelium.

are common veterinary practice. Specific essential, especially when chronic. In of malabsorption, intestinal biopsy tends to be required to obtain

efinitive unction erformed other onfirm ed or re vasive nostic rocedures.

Malassimilation may be classified by pathophysiologic process into maldigestive malabsorptive forms. Maldigestion results from altered gastric secretion lack of or decreased of digestive enzymes, which are usually secreted by pancreas often, by intestinal mucosa. Malabsorption often d cquired estinal or y cterial vergrowth omes. efore maldigestion are seen, approximately of pancreas must be ither nfunctional estroyed. estine dog tion ell ut re esult short owel ome," hich be ompensated or daptive chanisms.

Laboratory tests may evaluate gastric hydrochloric acid secretion, but of them are directed to detect malassimilation origin. Gastric acid secretion may be indirectly estimated by etermining astric uice rmal ogs ve gastric etween ric uice continuously nitored adiotelemetric echnique.

False-negative results may be caused by delayed gastric emptying, normal estinal ility, educed estinal lood w, bacterial overgrowth, sequestration of xylose ascitic

False-positive results may be caused by decreased glomerular

filtration rate; therefore, ensuring patient fully hydrated azotemic time of testing important.

oral dose of xylose, excreted through kidneys within hours. This test been improved by performing d-xylose 3-O-methyl-d-glucose absorption test com pares differential absorption of two sugars to eliminate nonmucosal effects of d-xylose absorption.

Serum concentrations of folate and cobalamin may be assessed by immunoassay. Both concentrations tend to be decreased with absorption. Folate absorbed proximal intestine, whereas cobalamin absorbed ileum. Bacterial overgrowth may also alter these concentrations; folate synthesis is increased with bacterial overgrowth, whereas some bacteria may decrease cobalamin availability. Assays for folate cobalamin (vitamin are usually performed conjunction with to evaluate extent of gastrointestinal disorders.

Synovial mucin forms clot when added to acetic acid. The nature of resultant clot reflects quality concentration of hyaluronic acid. method used to perform test involves adding of non-anticoagulated synovial to glacial acetic acid been diluted The synovial fluid/acetic acid solution gently mixed allowed to room temperature for before evaluated for presence of clot. The mucin clot generally graded good large, compact, ropy clot clear solution), soft clot slightly turbid solution), fair-poor friable clot cloudy solution), or poor actual clot, but some large flecks present turbid solution). Clot assessment enhanced by gently tube. Good clots remain ropy, whereas poor clots fragment. If only few drops of synovial are obtained with arthrocentesis, an abbreviated **mucin clot test** may be performed. If available after preparation of cytologic possibly after total nucleated cell count), drop of non–EDTA-preserved placed on clean microscope slide. Three drops of diluted acetic acid are added mixed. The resultant clot graded after approximately minute. Assess ment may be easier against dark background.

Numerous agents may be involved in common poisonings of dogs, horses, food These agents include herbicides, fungicides, insecticides, rodenticides, heavy metals (especially lead), household products (including phenols), automotive prod ucts (especially ethylene glycol), drugs (including medications), and various poisonous plants and animals. Often presumptive diagnosis may be attained from accurate history (including environmental factors) thorough clinical examination followed by response to therapy or by necropsy. However, establishment of specific etiologic diagnosis may be some few tests may be performed veterinary practice laboratory. In such situations, personnel must be competent with test procedure, reagents must be outdated, special equipment may be required. These requirements, together with sporadic demand for such tests, frequently dictate practitioners send all toxicologic specimens to specially equipped laboratory for analysis.

Suggestions for appropriate specimens preferred methods of handling, packaging, transport be obtained by consulta tion with toxicology laboratory. Such contact ensures laboratory offers procedures requested. Submitted specimens be free from contamination by extraneous environmental compounds or debris. Specimens be washed, because may remove toxic residues. Samples of different tissues, feeds must be submitted sepa rate, clean, leak-proof (airtight) plastic or glass containers. All containers be individually identified by owner's veterinarian's animal's or identification number, nature of specimen before packaged into large container for submission to laboratory.

Samples of whole blood usually heparin ized), serum (at least mL), vomitus, gastric lavage fluid, feces, urine (approximately may be submitted from live Samples of feed (portions of water, suspected may be helpful some In of poisoning, collected during thorough necropsy include whole blood or serum; urine; gut (especially stomach) contents g, noting site of collection); organ or tissue especially liver kidney but some times brain, bone, spleen, or (generally, where practi of each tissue). Sending too large always better sending enough, because excess be discarded.

In general, serum or blood are best submitted refrigerated, whereas gut contents tissues are best frozen. Preservatives are usually required. An exception would be tissue are submitted for histopathologic examina tion, which require fixation formalin must be frozen. If preservative used on specimen submitted for chemical analysis, probably worthwhile to submit aliquot of preservative for reference analysis. Frozen be insulated from other specimens arrive laboratory while they are still frozen. Dispatch to labora tory by courier recommended.

Because litigation may result from poisoning accurate detailed records be kept from outset of The establishment of good working relationship with toxi cology laboratory, including provision of good history necropsy findings of poisoning) when are submitted, helps to ensure best results.

The advantage of following tests they be performed reasonably quickly practice laboratory. Results are therefore available more rapidly were sent to toxicology laboratory. However, they are best viewed screening procedures be used to suggest appropriate avenues of investigation treatment. The verification of findings (especially positive ones) by reputable toxicology laboratory

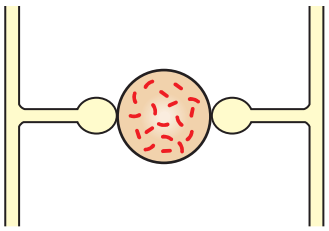
Unit Outline
Chapter 37: Introduction to Microbiology,
Chapter 38: Equipment and Supplies,
Chapter 39: Sample Collection and Handling,
Chapter 40: Staining Specimens,
Chapter 41: Culture Techniques,
Chapter 42: Antimicrobial Sensitivity Testing,
Chapter 43: Additional Testing,
Chapter 44: Mycology,

The Objectives for This Unit Are:
List and Describe the Supplies and Equipment Needed for Microbiology Testing.
Describe the General Characteristics of Bacteria and Fungi.
Discuss Sample Collection Procedures for Bacterial and Fungal Samples.
Describe Commonly Used Staining Procedures for Bacterial and Fungal Samples.
Describe Proper Techniques for Culturing Bacterial and Fungal Samples.
Describe the Proper Procedure for Antimicrobial Sensitivity Testing.
Describe the Procedure for Performing the California Mastitis Test.
List and Describe Common Biochemical Tests Performed on Bacterial Samples.

Microbiology refers to the study of microbes. Microbes are organisms that are too small to be seen with the unaided eye. Bacteria, fungi, and viruses are all microbes. Some parasites are also considered microbes. The fields of study of bacteria, fungi, and viruses are referred to as bacteriology, mycology, and virology, respectively. Virology evaluations in the veterinary clinical laboratory are usually performed with immunologic methods. Bacteria and fungi can be evaluated with a number of routine microbiology procedures. Although some prac tices send all microbiology work to a reference laboratory, most practices do some testing in-house. Bacterial and fungal samples can be collected quickly, easily, and inexpensively, and tests do not require much in the way of specialized equipment. Careful attention to quality control is vital to ensure the diagnostic value of results.

Most microbes found on and in the body are nonpathogenic (i.e., they are normal flora). The intestinal and respiratory tracts, the skin, and parts of the urinary and reproductive tracts all have known normal flora. Samples collected from some locations, such as the spinal column, the blood, and the urinary bladder, should be free of normal flora. Microbes that are considered normal flora and nonpathogenic when found in one location can produce significant disease if they are found in a site where they should not reside.

For additional sources for this unit see the Resources Appendix at the end of this textbook.



Introduction to Microbiology

After studying this chapter, you will be able to:

- Describe eneral haracteristics cteria, viruses.
- Discuss cteria rowth haracteristics equirements for rowth.
- Describe haracteristic rangements bacteria.
- Discuss nificance ore ormation cteria fungi.
- Describe eproduction rganisms.
- Differentiate roups genic
- Discuss eneral thods or iral ecimen ollection handling.
- List thods or valuation suspected iral gens.

Most virologic techniques are performed specialized labora tories. They include histopathologic serologic examination, electron microscopy, attempted isolation identifi cation of virus. The veterinary technician contact diagnostic laboratory to check which facilities are available, which are preferred, whether transport medium necessary. If exotic reportable suspected, proper authorities be notified, clinical material be removed from facility.

Many of viral encountered may be diagnosed on clinical pathologic grounds. Serologic tests are available for viral Some may require paired serum are collected to weeks apart, starting during early stages of rising antibody titer indicates recent infection by virus.

Virus isolation expensive time-consuming, may provide only diagnosis after have recovered or died. However, some instances, isolation identification of virus be attempted, such to establish identity of viral previously seen practice, to discover exact agent when serologic other tests have given equivocal results, to immunologic type of virus epizootic, to verify etiologic agent public problem involved.

The isolation of virus from diseased does necessarily virus caused because many viruses persist without clinical signs of illness. Some other pathogen or condition could have been responsible for Virus isolation successful when speci mens are collected early during active infectious phase of

Viruses vary greatly with regard to their ability to remain viable tissues exudates. Contamination with bacteria greatly decreases success of attempted virus isolation. Specimens are selected on of their likelihood to contain large numbers of virus particles. Samples for virology testing must be collected aseptically, kept taken to laboratory shortest time possible.

To demonstrate presence of virus specimen, virus grown (isolated) laboratory, or virus antigens or antibodies are assayed. Unlike bacteria, which be grown on nutrient agar, viruses need living cells which to grow replicate. The tissue cells are placed into suitable glass bottle or chamber containing medium rich nutrients. The cells settle begin to grow confluent monolayer across the surface of the container. Various types of cells have been used for tissue culture of viruses. Most cells be grown vitro for some generations, but some cells divide indefinitely are used for virus isolation. These cells are called continu cell they are of single type of cell. Continuous cell such from fetal kidney, embryonic trachea, other cells, are derived from monkeys, dogs, pigs, mice, hamsters, rabbits, other The virus specimen commonly inoculated into primary culture of cells derived from species of from which specimen taken.

After cell culture been inoculated with virus speci men incubated, examined. If virus present, cell damage may be visible virus particles invade tissue cells. This damage referred to cytopathic effect. Different types of cytopathic effects are used to identify viruses. Some viruses cell lysis, others cells to form syncytiae (sheets) giant cells. An inclusion body another type of cytopathic effect may be seen.

Clinical signs cell culture examination may identify virus to family level perhaps to genus species level, but definitive identification requires serologic procedures are based on immunologic principles. Sometimes serologic procedures may be used on specimens directly, which saves time expense of cell culture. In-house diagnostic tests are available to detect presence of some common viral pathogens. Unit contains more details about immunologic tests used for detection of viral antigens antibodies.

Molecular diagnostic tests (e.g., polymerase chain reactions) are routinely used for identification of pathogens. These are discussed Unit

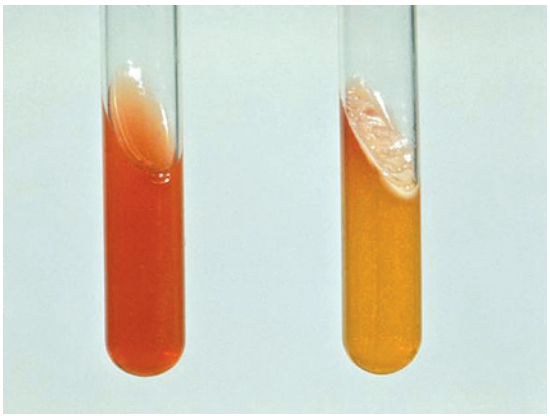
If the organism can ferment lactose, sucrose, or both in addi tion to glucose, lactose sucrose are then attacked with resulting acid production, medium turns yellow (acidic) throughout. Lactose sucrose are present quantities to cidic onditions hich emains ellow.



their ability to ferment glucose, lactose, or sucrose as well as to produce

result indicates no fermentation. (Courtesy Public Health Image Library,

With organisms produce hydrogen sulfide, blackening of medium partly superimposed on other reactions. The triple sugar iron be read after about hours of incubation After longer incubation, blackening tends to reach bottom of tube obscures yellow butt.

The following summarizes the reactions of *Salmonella* species triple sugar iron agar:

- Alkaline (red) (red) butt: none of sugars attacked
- Alkaline (red) acidic (yellow) butt: glucose fermentation only
- Acidic (yellow) acidic (yellow) butt: glucose attacked addition to lactose, sucrose, or both
- Blackening along through medium: hydrogen sulfide production

The triple sugar iron inoculated with single colony from selective medium with straight inoculating wire. The wire pushed down to bottom of agar, when withdrawing wire, agar streaked. The inoculating wire still contains enough bacteria to inoculate tube of lysine decarboxylase broth. During search for salmonellae, two suspicious colonies be individually tested triple sugar iron agar per brilliant green plate. The triple sugar iron tubes be incubated, with loose for to hours.

Brain–heart infusion broth useful general-purpose broth used to increase number of organisms (preenrichment) before they are plated on medium. The broth inoculated with patient subcultures are taken needed for additional testing.

For culture of blood approximately of patient's blood added to nutrient broth or to special blood culture medium be obtained commercially. Because patient's blood contains many substances are inhibitory to bacteria, adding blood directly to broth dilutes effect of natural inhibitors.

Mannitol agar routinely used, but highly selective medium for staphylococci, could be used to isolate *Staphylococcus aureus* from contaminated specimens. The medium high content contains mannitol indicator phenol red. Staphylococci are tolerant. *S. aureus* (but usually *Staphylococcus epidermidis* ferments mannitol. The resulting acid turns *S. aureus* colonies surrounding medium yellow.

In selective medium, freshly precipitated bismuth sulfite acts with brilliant green to suppress growth of coliforms while permitting the growth of salmonellae. Sulfur compounds provide substrate for hydrogen sulfide production. The metallic medium colony surrounding medium black or brown presence of hydrogen sulfide.

Atypical colonies may appear medium heavily inoculated with organic matter. This situation may be prevented by suspension of sterile of supernatant for inoculation.

The freshly prepared medium strong inhibitory action, suitable for heavily contaminated Storing poured plates for days medium to change color to green, thereby selective, with small numbers of salmonellae being recovered.

The following summarizes typical appearance of more important bacterial organisms on bismuth sulfite agar appearance of their colonies:

Salmonella typhi: black "rabbit eye" colonies, with surround black zone metallic sheen after hours; uniformly black after hours of incubation

- Other *Salmonella* species: variable colony appearance after hours (black, green, or clear mucoid); uniformly black colonies seen after hours, often with widespread of medium pronounced metallic sheen
- Other organisms (coliforms, *Serratia* *Proteus* species): usually inhibited but occasionally dull green or brown colo with metallic sheen or of surrounding medium

Mueller-Hinton agar general-purpose medium primarily used for performance of agar diffusion antimicrobial sensitivity test. The chemical composition of the media does not interfere with diffusion of antimicrobials through agar.

Both of media are used specifically for culture of fungi yeasts. Bismuth–glucose–glycine–yeast agar commonly referred to "biggy." Dermatophyte test media found veterinary clinics composed of **Sabouraud dextrose agar**

Chapter 47: Protozoa and Rickettsia,
Chapter 48: Arthropods,
Chapter 49: Sample Collection and Handling,
Chapter 50: Diagnostic Techniques,

The objectives for this unit are:
List the common internal parasites of domestic animals.
List the common external parasites of domestic animals.
Discuss the life cycles of common parasites of domestic animals.
Describe the treatment and control strategies for common parasites of domestic animals.
Describe the procedures that are used to diagnose parasites.

Parasitology is the study of organisms that live in (internal parasites, endoparasites) or on (external parasites, ectoparasites) another organism, the host, from which they derive their nourishment. Parasitism is a type of symbiotic relationship. Symbiosis involves two organisms living together, and there are three types: (1) Com mensalism: One organism benefits, the other is unaffected; (2) Mutualism: Both organisms benefit; and (3) Parasitism: One organism benefits, the other is harmed.

The organism that the parasite lives in or on is called its host. The host may be a definitive host that shel ters the sexual, adult stages of the parasite, or the host may be an intermediate host that harbors the asexual (immature) or larval stages of the parasite. There are also paratenic hosts or transport hosts for some para sites, in which the parasite survives without multiplying or developing. Parasite life cycles can be simple with direct transmission, or they may be complex and involve one or more vectors. A vector can be mechanical or biological. Mechanical vectors transmit the parasite, but the parasite does not develop in the vector. Biological vectors serve as intermediate hosts for the parasite. The term life cycle refers to the maturation of a parasite through various developmental stages in one or more hosts. For a parasite to survive, it must have a depend able means of transfer from one host to another and the ability to develop and reproduce in the host, ideally without producing serious harm to the host. This requires the following:

A mode of entry into a host (infective stage)

The availability of a susceptible host (definitive host)

An accommodating location and environment in the host for maturation and reproduction (e.g., the gastro intestinal, respiratory, circulatory, urinary, or reproductive system)

A mode of exit from the host (e.g., feces, sputum, blood, urine, smegma), with dispersal into an ecologically suitable environment for development and survival

Parasites have a wide distribution within host animals. They can have a negative impact in a number of ways, including the following:

Injury on entry (e.g., creeping eruption)

Injury by migration (e.g., sarcoptic mange)

Injury by residence (e.g., heartworms)

Chemical or physiological injury (e.g., digestive disturbances)

Injury due to host reaction (e.g., hypersensitivity, scar tissue)

Internal parasites, called endoparasites, live within an animal. These parasites derive their nutrition and protection at the expense of the infected animal, which is called the host. The various internal parasites have many different life cycles. Each parasite's life cycle is distinctive. It is composed of various developmental stages, all of which may occur within the same host or separately within sequential hosts. Endoparasites of domestic animals include unicellular protozoans, trematodes (flukes), cestodes (tapeworms, with their associ ated metacestode stages), nematodes (roundworms), and acanthocephalans (thorny-headed worms). A few arthropods (e.g., horse bots) are endoparasites. Ectoparasites usually live on or in skin surfaces or feed on them. Ectoparasites infest the skin or external surfaces of animals and produce an infestation on the animal.

The host that harbors the adult, mature, or sexual stages of a parasite is called the definitive host. The dog is the definitive host for *Dirofilaria immitis;* adult male and female heartworms are found in the right ventricle and pulmonary arteries of the dog's heart. The host that harbors the larval, immature, or asexual stages of a parasite is called the intermediate host. The mosquito is the intermediate host for *immitis;* the first, second, and third larval stages of *D. immitis* are found within the mosquito.

The life cycle of most parasites has at least one stage during which the parasite may be passed from one host to the next. Diagnostic procedures frequently detect this stage; therefore, it is referred to as the diagnostic stage. The diagnostic stage of a parasite may leave the host through excreta (e.g., feces, urine), or it may be transmitted from the bloodstream to its next host by an arthropod (e.g., a mosquito). The microfilarial stage is the diagnostic stage of *D. immitis;* the female mosquito takes in the microfilariae during a blood meal.

The diagnosis of endoparasitism is one of the most frequently performed procedures in the veterinary clinical setting. An accurate diagnosis of endoparasitism is based primarily on the veterinarian's and the technician's awareness of parasites that are prevalent in the immediate geographic area or ecosystem. However, because of the far-ranging mobility of owners and their pets in the twenty-first century, residence in or travel to another geographic region should also be considered when endoparasitism is among several differential diagnoses.

Heavily parasitized animals often show clinical signs that are suggestive of the infected organ system. Depend ing on the affected organ system, these signs may include diarrhea or constipation, anorexia, vomiting, blood in the stool, or fat in the stool. Parasitized animals are frequently lethargic and display an unthrifty appearance that is characterized by weight loss or stunted growth, a dull hair coat, dehydration, or anemia. The animal may also experience coughing or labored breathing.

Internal parasites of domestic animals comprise several types of organisms that live internally in animals, that feed on their tissues or body fluids, or that compete directly for their food. These organisms range in size from being too small to be seen with the naked eye (microscopic) to being more than 1 ngth. Parasites also vary with regard to their location within the host and the means by which they are transmitted from one host to another. Because of these diverse variations, no single diagnostic test can identify all endoparasites.

The time elapsed between initial infection with a parasite until the infection can be detected with the use of common diagnostic procedures is called the prepatent period. The best example of this concept is trying to diagnose hookworm disease *(Ancylostoma caninum)* in a 1-week-old puppy via the observation of eggs on fecal flotation. This attempted diagnosis is not helpful, because the minimum time from infection until adult hookworms are present in the bowel and begin to produce eggs (prepatent period) is 12 days. The astute veterinary practitioner uses fecal flotation results but also the puppy's history, clinical signs, and other labora tory tests (e.g., blood values) to arrive at a specific diagnosis of ancylostomiasis (infection with hookworms).

Classification of Parasites. Parasites of domestic animals are found in the kingdom Protista and the kingdom Animalia as well as in a large number of phyla in those kingdoms. There is some variation with regard to the classification schemes of different references, and organisms are often reclassified when new information about their biochemistry is obtained. In Appendix G, the box entitled "Kingdom: Animalia (Animals)" contains a summary of the taxonomic classifications of common parasites of domestic animals.

The majority of information in this unit is related to parasites of companion and farm animals. Lists of the major parasites of exotic species are located in Appendix E

Zoonoses. Zoonoses are diseases that can be transmitted between animals and humans. Veterinary technicians are responsible for educating clients about preventing infection with zoonotic parasites. Parasites of zoonotic significance include protozoans, trematodes, cestodes, nematodes, and arthropods. Commonly encountered zoonotic parasites are summarized in Appendix H entitled "Zoonotic Internal Parasites."

For additional sources for this unit see the Resources Appendix at the end of this textbook.

After studying this chapter, you will be able to:

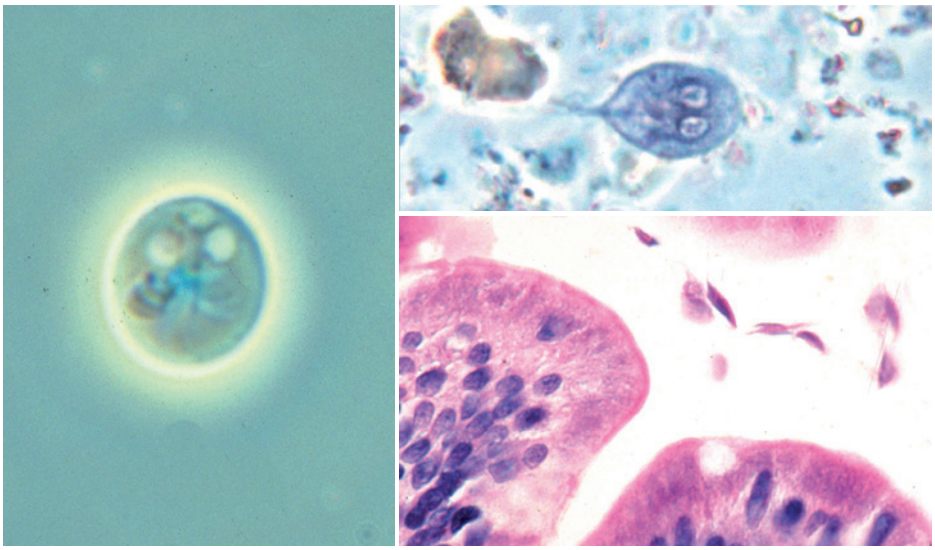
Select Protozoal Parasites of Veterinary Species

	Intermediate		Intermediate
Isospora ohioensis			

Organelles for locomotion consist of **flagella** (long, whiplike structures), (short flagella, usually arranged rows or tufts), **pseudopodia** (temporary extensions retractions of body wall), **undulatory ridges** (small, snakelike waves form cell membrane move posteriorly). Locomotor organelles modifications of them are frequently used to help identify the type of protozoa recovered from an animal. The trophozoite often too fragile to survive transfer to new generally infective. Transmission to often occurs when protozoan cyst stage. Most metabolic functions are suspended when parasite encysted. The cyst wall prevents desiccation. The cyst stage occurs under certain conditions include following:

- Lack of nutrients
- Low oxygen tension
- Lack of water
- Low
- Accumulation of waste
- Overcrowding

Protozoal parasites are usually transmitted to a new



trophozoite in a trichrome-stained fecal smear.

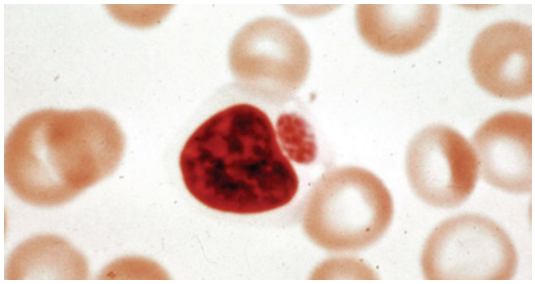
cally parasitized erythrocytes and an immature form. (Courtesy Raymond

fungal agents of animal disease,



fungal agents of animal disease,

- Parasitic protozoa be found three primary phyla: Sarcomastigophora, Apicomplexa, Ciliophora.
- Protozoal parasites are usually transmitted to new during cyst stage.
  Giardia species common flagellate infect variety of including humans.
- Trypanosomes *Leishmania* species are zoonotic parasites are primarily found southern United States.
  Tritrichomonas foetus parasite of reproductive tract of infertility, spontaneous abortion, pyometra.
- Apicomplexans (sporozoans) are found within cells, they commonly occur intestinal tract cells blood cells.
- Cats are only definitive for *Toxoplasma gondii,* various life-cycle stages of parasite infect other species, including humans.
  Cytauxzoon felis intracellular parasite sporadically found of usually
- A variety of *Eimeria* species are capable of infecting ruminants small
- Rickettsia are obligate intracellular parasites with two primary taxonomic Rickettsiaceae Anaplasmataceae.

parasitic mites are obligate parasites, which spend their entire life cycle on produce dermatologic condition referred to **mange** few species found on birds rodents live off of visit only to obtain blood (e.g., *Dermanyssus gallinae, Ornithonyssus bacoti* Most mite infestations are transmitted through direct contact with infested Burrowing mite infestations are diagnosed with deep scrapings periphery of lesions.

The first group of parasitic mites be classified together sarcoptiform mites. Sarcoptiform mites have several common key characteristics or features. These mites may produce severe dermatologic problems variety of domestic The dermatitis produced by mites usually accompanied by severe pruritus. Sarcoptiform mites are barely visible to naked eye, they are approximately size of grain of Their bodies are round to oval. Sarcoptiform mites have legs with pedicels or tip. The pedicels may be long or short. If pedicel long, may be straight (unjointed) or jointed. At tip of each pedicel may be tiny sucker. The description of pedicel (e.g., long or short, jointed or unjointed) may be used to identify sarcoptiform mites. Another group of mites parasitic only larvae trombiculid mites or "chiggers."

Diagnostic Characteristics of Internal Parasites of Domestic Animals—cont'd

Diagnostic Characteristics of Internal Parasites of Domestic Animals—cont'd

From Sirois M: *Principles and practice of veterinary technology,*

Diagnostic Characteristics of Blood Parasites of Domestic Animals

From Sirois M: *Principles and practice of veterinary technology,*

- Methods for examination of fecal specimens include both gross microscopic examination of feces.
- The microscopic examination of fecal samples may involve the direct examination of or concentration of material with fecal flotation or fecal sedimentation techniques.
- Hemoparasites (blood parasites) be identified with micro scopic examination of peripheral blood smears or by variety of concentration techniques (e.g., modified Knott's procedure).
- Fecal concentration methods are preferred for identifica tion of parasite ova, larvae, oocysts feces. Larger volumes of feces are used compared with direct smear, thereby more likely developmental stages will be seen, present, feces.
- Fecal flotation solutions with specific gravity of to are used to float parasite ova, cysts, larvae while fecal material to bottom of container.
- The fecal solutions of choice are Sheather's sugar solution, sodium nitrate solution, sulfate solution.
- Fecal centrifugation method of choice for fecal flotation testing, because floats higher concentration of ova, cysts, larvae compared with fecal flotation.
- Fecal sedimentation used to test for trematode eggs, which are heavier other parasite eggs thus do float well.
- •A blood will reveal such blood parasites *Babesia* *Theileria* within red blood cells. However, be used for accurate differentiation of *D. immitis* *A. reconditum*
- The buffy coat technique and the modified Knott's technique be used to properly differentiate between *D. immitis* *A. reconditum*

Unit Outline
Chapter 51: Sample Collection and Handling,
Chapter 52: Preparation of Cytology Smears,
Chapter 53: Microscopic Evaluation,
Chapter 54: Cytology of Specific Sites,

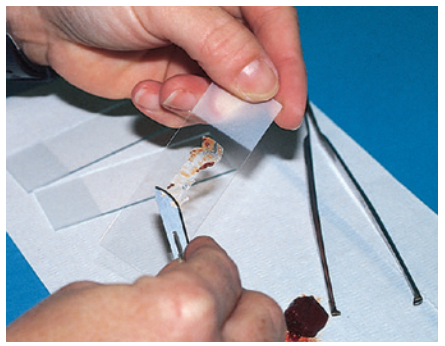
The objectives for this unit are:
Describe the collection and handling of cytology samples.
Describe the preparation techniques that are used with cytology samples.
Discuss the general procedure for the evaluation of cytology samples.
Describe the general characteristics of samples taken from inflammatory lesions.
Describe the general characteristics of samples taken from neoplastic lesions.
Discuss the microscopic appearance of cells in cytology samples taken from a variety of sites.

Exfoliative cytology is the study of cells that have been shed from body surfaces. It refers to the examination of cells that are present in body fluids (e.g., cerebrospinal, peritoneal, pleural, and synovial fluids), on mucosal surfaces (e.g., in the trachea or vagina), or in secretions (e.g., semen, prostatic fluid, milk). The primary purpose of the cytology evaluation is to differentiate inflammation from neoplasia. The types and numbers of cells that are present in a properly collected and prepared cytology specimen can provide rapid diagnostic information to the clinician. Samples for cytology evaluation can be collected quickly and do not generally require special ized materials or equipment for proper evaluation. With careful attention to quality control—including the use of appropriate collection, preparation, and staining techniques—a high-quality cytology sample can be obtained. Such samples yield valuable results for the clinician and often preclude the need for more invasive procedures to determine a patient's diagnosis, treatment, and prognosis.

Cytology provides somewhat different information than a histopathologic evaluation. Histopathology observes cells in relation to their neighboring cells. The histopathologist evaluates the cellular architecture. The prepara tion of a sample for histopathology involves several complex steps and some specialized equipment. To prepare a sample for histopathology, the tissue is first immersed in fixative. Several steps are involved in dehydrating the tissue before it is imbedded in paraffin. The paraffin block is then sliced, and the slice is mounted on a glass slide before it is stained. Cytologic evaluations observe the cells individually or in small groups. The cells in a cytologic preparation are randomly distributed, with no evidence of their in vitro relationship to each other.

For additional sources for this unit see the Resources Appendix at the end of this textbook.

Sample Collection and Handling



After studying this chapter, you will be able to:

- List echniques or ollection cytology
- Describe rocedure or ollecting bing.

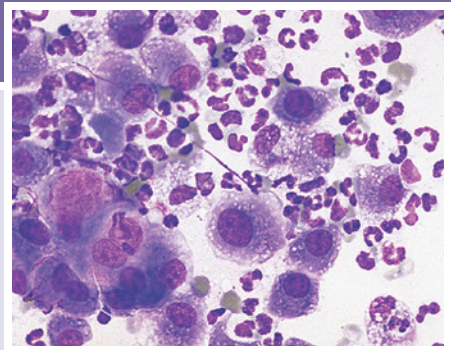
Problems That Can Occur With Romanowsky Stains and Proposed Solutions

Excessive Blue Staining (RBCs May Be Blue-Green)

Precipitate on Preparation

- Commonly performed methods for preparation of for cytologic evaluation include compression smear, smear, combination methods.
- Fluid be prepared with compression or smear.
- Preparation methods are based on characteristics of volume of obtained.
- A variety of preparation methods may be needed, and multiple preps are usually made.
- The compression preparation commonly used method.
- Line smears are preferred when volume small cellularity low.
- Cytology slides are fixed with methanol before they are stained.
- Most cytology be stained with Romanowsky



After studying this chapter, you will be able to:

- Describe eneral rocedure or valuation cytology
- Describe eneral pearance om inflammatory
- Describe eneral pearance om neoplastic
- State uclear iteria nancy.
- Differentiate etween uppurative, ranulomatous, pyogranulomatous, osinophilic ion.
- Describe eneral umor ypes.
- State haracteristics om ch general egories umors.

The olume jaculate ured olumetric which may be incorporated into collection receptacle. Marked species ariations ccur, thod ollection reatly influences olume btained, ross pearance, spermatozoal concentration. generalization, ejaculate volume larger but spermatozoal concentration lower specimen

apparently more dilute) when collected by electroejaculation when collected with artificial vagina. In addition, repeated ejaculation—whether associated with semen collection or sexual activity—decreases the volume and concentration of semen obtained subsequent collections. Semen volume tends to be greater collection preceded by period of sexual arousal "teasing").

The ejaculate composed of three portions: sperm-free watery secretion, sperm-rich fraction, sperm-poor frac tion. The first third fractions are derived from accessory sex glands. In bucks, bulls, rams, toms, all three fractions are collected together. However, with boars, dogs, stallions, third fraction conveniently may be collected separately, which advisable, because third fraction voluminous three therefore unnecessary encumbrance during subsequent evaluation of semen In three species, first two fractions (collected together) are used other procedures follow.

The approximate average total ejaculate volumes (all three fractions) are follows: boar, buck ram, bull, dog, stallion, tom, Ejaculate volume does necessarily correlate with fertility. In general, spermatozoal number, motility, morphologic characteristics are better guides to fertility. However, small ejaculates may be of concern species have voluminous ejaculates. Knowledge of ejaculate volume necessary to determine total spermatozoal numbers to be divided possibly diluted) for artificial insemination procedures.

The opacity color of be recorded. Opacity subjectively reflects the concentration of spermatozoa. Categories used include thick, creamy, opaque; milky opaque; opalescent milky; watery white. This generalization works best for semen from bucks, bulls, rams, which normally have opaque, creamy-white semen because of high spermatozoal concentration. As density of spermatozoa decreases, specimen becomes more translucent and milkier in appearance. Semen from boars, dogs, stallions normally fairly translucent white to gray. Contaminants, especially intact or degenerate erythrocytes, discoloration of semen.

Sperm motility (movement) is subjectively assessed and depends on careful handling of for meaningful results. Variations temperature exposure to nonisotonic or destructive chemicals (including detergents) must be avoided. Motility correlated with fertility; however, improper specimen handling adversely affects assessment. If other tests (especially sperm morphology) suggest semen normal but sperm motility poor, another be examined to ensure technical errors were responsible for poor motility. Motility may be conveniently assessed two ways.

Wave motion subjective assessment of gross motility of sperm. Four general classifications are used—very good, good, fair, poor—on of of swirling activity observed drop of semen on microscope slide low power magnification. These categories respectively correspond to distinct vigorous swirling, moderate slow swirling, barely cernible swirling, lack of actual swirling but with motile sperm present, which may to have irregular oscillating appearance. Wave motion depends on high sperm density therefore best from bucks, bulls, rams, which normally have high sperm concentrations. Wave motion decreases sperm concentration decreases. Consequently, normal boars, dogs, stallions, toms may have or poor wave motion. As guide, wave motion very good or good, be diluted for evaluation of percentage of motile sperm their rate of motility.

The progressive motility of individual spermatozoa determined on relatively dilute drop of semen under coverslip examined magnification. Because motility of vidual spermatozoa to appreciate dense such concentrated be diluted before examination. Warm physiologic or fresh buffered sodium citrate solutions are suitable diluents.

drop of semen placed on slide diluted until satis factory concentration of spermatozoa observed. coverslip placed on top to produce monolayer of cells. Excessive dilution of makes evaluation of motility The rate of motility generally subjectively classified very good, good, fair, or poor, which corresponds to rapid activ ity, moderate activity, slow or erratic activity, very slow erratic activity, respectively. The percentage of motile spermatozoa broadly categorized very good, good, fair, or poor, which corresponds to approximately to to to motile cells, respectively. Satisfactory have moderately active spermatozoa.

Several solutions are satisfactory for semen dilution before sperm numbers are counted, including of sodium bicarbonate or of sodium chloride with of formalin of distilled water; chlorazene; or of sodium sulfate with of glacial acetic acid of distilled water (Gower's solu tion). dilution made, counted hemocytometer. The number of spermatozoa central grid area of one side of chamber counted nification. The number of spermatozoa per milliliter of semen calculated by multiplying number observed by million. If spermatozoal concentration high (e.g., bucks, bulls, toms), fewer squares may be counted multiplica tion factor adjusted accordingly. Spermatozoal concentration may be determined by colorimetric electronic particle counter techniques.

Depending on collection method, average sperm con centrations millions per milliliter) are approximately for boars stallions, for bucks rams, for bulls, for dogs, for toms.

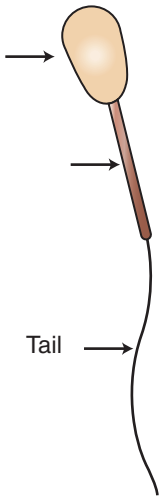

Diagram of a normal spermatozoa.

Chapter eview uestions ppendix

- Peritoneal pleural are evaluated for color, transpar ency, dor,
- Cells e ounted lassified om eritoneal ural

- The evaluation of cellular elements allows to be classified exudates, transudates, or modified transudates.
- In normal lymph node, predominant cell type small, mature lymphocyte.
- Reactive lymph nodes contain predominantly small, mature lymphocytes well cells, lymphoblasts, inter mediate lymphocytes.
- Evaluations performed on synovial include ment of color turbidity; cytologic examination of direct smear; the subjective assessment of viscosity; and mucin test, refractometric protein measurement.
- Abnormal tracheal are generally exudates.
- Yeasts, squamous epithelial cells, *Malassezia* organisms are commonly isolated from may indicate pathology.
- Vaginal may contain variety of epithelial cells addi tion to neutrophils erythrocytes.
- Epithelial cells are present vaginal cytology may include small cells, slightly larger parabasal epithelial cells, noncornified squamous epithelial cells (intermediate cells), cornified epithelial cells.

here are hazards associated with specific chemicals described?
aterial Safety Data Sheets
. azard Communication Standard
athogen Standard
IM Guidelines

he bacterial agent that causes toxoplasmosis is classified as having which biohazard level?
.
. II

hat agency mandates regulations related to the safe ship ment of potentially hazardous or infectious materials?
ederal Aviation Administration
. .S. Department of Agriculture
cupational Safety and Health Administration
.S. Department of Transportation

4. rue or False: Chemicals transferred into secondary contain ers always require special hazard labeling.
True
. False

rue or False: The use of personal protective equipment (e.g., lead-lined x-ray gloves) is optional.
True
. False

hich regulation describes the scope and extent of worker training and the documentation of that training?
rocedural Control Listing
. C Biosafety Standard
hemical Hygiene Plan
E Standard

rue or False: Most diagnostic samples from veterinary patients sent to outside laboratories for analysis fall into Category B.
True
. False

nfectious canine hepatitis is classified as which biohazard level?
.
. II

9. hich government agency is responsible for enforcing safety regulations in the workplace?
CDC
.
. DOT
FAA

he use of a fume hood when handling chemicals is an example of which approach to minimizing workplace hazards?
ineering controls
. dministrative controls
rocedural controls
ersonal protective equipment

hich is used to calibrate the refractometer?
ontrol serum
b. efractometer standard
istilled water
ormal saline

hat designation is used to describe a pipette that has a double-etched or frosted band at the top?
To contain"
. To deliver with blow-out"
To deliver"
To contain with rinsing"

hich type of pipette is used only to add liquid to another liquid and must then be rinsed with the first liquid?
To contain"
. To deliver with blow-out"
olumetric
ransfer

4. hat is used to clean the optical surface of the refractometer immediately after use?
oap and water
b. ylene
imwipes
ens paper

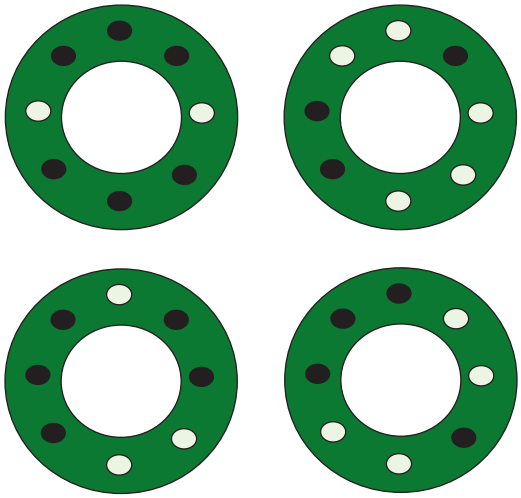
hat type of tube is used to prepare a urine sample prior to centrifugation?
erile
b. lood collection

onical
icrohematocrit

6. hat item is required for the processing of blood components?
d clinical centrifuge
b. ngled-head centrifuge
efrigerated centrifuge
d centrifuge

hich of the following does *not* require an adapter for use with different sizes of test tubes?
imple standard water baths
b. eat blocks
irculating water baths
aterless bead baths

8. hich of the following diagrams depicts a properly balanced centrifuge?



hat is the final magnification of a specimen being viewed via a 10 ocular objective and a 40 objective lens?

b. 0
c.

hich term is used to describe flat field objective lenses?
a. bbe
b. chromatic
pochromatic
igh-eyepoint

hich component of the microscope functions to aim and focus the light that is illuminating the specimen?
a. ondenser
b. osepiece
ris diaphragm
perture diaphragm

rue or False: Mineral oil can be used in place of immersion oil with the oil-immersion lens.
rue
b. alse

hich component of the microscope regulates the amount of light that is illuminating the specimen?
a. ondenser
b. osepiece
ris diaphragm
oarse adjustment knob

hat is the final magnification of a specimen being viewed via a 10 ocular objective lens and a 100 objective lens?

b.

hat is the preferred cleaning solution to be used for the routine cleaning of microscope lenses?
ethanol
b. ylene
ineral oil
mmonia

hat is the preferred cleaning solution to be used for the removal of excess oil from the microscope lenses?
ethanol
b. ylene
ineral oil
mmonia

hich measurement is equal to 1

.

2. hat is the final dilution of a solution that contains 20 dL of a substance that is diluted 1

.

hich number is equal to the number that is written in scientific notation as 10

.

ater freezes at _____° according to the Fahrenheit scale and at _____° according to the Celsius scale.
32
. 212
0
d. 273; 0

ow is the number 624,012 written in scientific notation?

.

ow is the number 0.024 written in scientific notation?

.

ng (nanogram)

.

ow many milliliters are in a 1-L bag of 0.9% NaCl solution?

.

o prepare a 1 ution of a patient sample, combine _____ of the sample with _____ of distilled water.
L; 90
. L; 100
mL; 90
mL; 100

ow is the number 9700 written in scientific notation?

.

hich term refers to how close a test result is to the actual patient value?
ensitivity
b. ecificity
recision
ccuracy

hich term refers to the reproducibility of a test result?
ensitivity
b. ecificity
recision
ccuracy

hich term describes a product that is analyzed in the same manner as a patient sample and used to verify test results?
ontrol
b. d
eagent
alibrator

hich term describes the ability of a testing method to be accurate and precise?
eproducibility
b. eliability
recision
ccuracy

5. ollecting a blood sample from a patient that is not properly fasted is an example of which type of error?
reanalytic
b. nalytic
ostanalytic
onbiologic

6. n improperly maintained analyzer can introduce which kind of error into a test result?
reanalytic
b. nalytic
ostanalytic
onbiologic

---

1. emoglobin formation begins during the _____ stage of erythrocyte maturation and ends during the _____ stage.
ubricyte; metarubricyte
. ubricyte; reticulocyte
ubriblast; reticulocyte
etarubricyte; reticulocyte

hat is the primary cytokine involved in the stimulation of erythrocyte production?
Leukopoietin
. Erythropoietin
Thrombopoietin
Hematopoietin

hat is the primary cytokine involved in the stimulation of platelet production?
Leukopoietin
. Erythropoietin
Thrombopoietin
Hematopoietin

hat is the primary cytokine involved in the stimulation of leukocyte production?
Leukopoietin
. Erythropoietin
Thrombopoietin
Hematopoietin

hat is the primary site for the production of blood cells in the neonatal and juvenile animal?
Liver
. ed bone marrow
Spleen
ellow bone marrow

hat is the primary site for the production of blood cells in the adult animal?
Liver
. ed bone marrow
Spleen
ellow bone marrow

7. he cells in the erythrocyte maturation series in order from most immature to most mature are:
ubricytes, rubriblasts, proreticulocytes, reticulocytes
. roreticulocytes, metarubricytes, rubricytes, reticulocytes
ubriblasts, prorubricytes, metarubricytes, rubricytes, reticulocytes
ubriblasts, prorubricytes, rubricytes, metarubricytes, reticulocytes

8. he cells in the granulocyte maturation series in order from most immature to most mature are:
romyeloblast, myeloblast, myelocyte, metamyelocyte, band cell
. yeloblast, promyelocyte, metamyelocyte, myelocyte, band cell

yeloblast, promyelocyte, myelocyte, metamyelocyte, band cell
yeloblast, myelocyte, promyelocyte, metamyelocyte, band cell

9. fter a granulocyte matures to the _____ stage, it begins to exhibit granules that are characteristic of the neutrophil, the eosinophil, or the basophil.
Myeloblast
. Promyelocyte
Myelocyte
Metamyelocyte

hich cells are part of the granulocyte proliferation pool?
etamyelocytes and band cells
. yeloblasts, promyelocytes, and myelocytes
yeloblasts and metamyelocytes
romyelocytes and metamyelocytes

11. hich term describes a decrease in the numbers of all blood cells and platelets?
Pancytopenia
. Erythropenia
Reticulocytosis
Polycythemia

hat is meant when a sample is described as having a left

Neutrophilia
. shift in the neutrophil–lymphocyte ratio in favor of neutrophils
n increase in the number of immature neutrophils in the blood
ukemoid response

he Vacutainer that is most suitable for collection of blood for hematology usually has a _____ colored top.
. Red
. urple or lavender
. Green
Blue

hich anticoagulant is preferred for routine hematologic studies because it preserves cell morphology?
Heparin
. odium citrate
EDTA
mmonium oxalate

3. hat is the preferred site for venipuncture in large animals?
ammary vein
. ugular vein
nfraorbital sinus
ail vein

4. hich site is preferred for venipuncture in dogs when small volumes are needed?
ephalic vein
. ugular vein
aphenous vein
emoral vein

hich term describes the fluid portion of the blood that contains no formed elements or fibrinogen?
hole blood
. lood plasma
nticoagulated blood
Serum

hich anticoagulant provides the best preservation of glucose?
Heparin
. odium fluoride
EDTA
mmonium oxalate

hat can occur if a tourniquet is left in place for an excessive amount of time?
Hemolysis
. Icterus
Hemoconcentration
Lipemia

hen collecting samples from a patient who requires hematology, chemistry, and coagulation testing, the first sample collected will be the one that requires _____ anticoagulant.
. No
. Fluoride
EDTA
Citrate

9. hen collecting samples from a patient who requires hematology and chemistry testing, the first sample collected will be the one that requires _____ anticoagulant.
. No
. Fluoride
EDTA
Citrate

hat is contained in the "tiger-top" blood collection tube?
EDTA
. Oxalate
l separator
Silicone

hich type of analyzer counts particles on the basis of their size?
mpedance counter
. itative buffy coat analyzer
efractometer
r flow cytometer

hich type of instrument counts particles on the basis of their relative size and density?
mpedance counter
. itative buffy coat analyzer
efractometer
r flow cytometer

3. hich instrument provides an estimate of cell counts on the basis of differential centrifugation?
mpedance counter
. itative buffy coat analyzer
efractometer
r flow cytometer

unning the electrolyte solution through the impedance counter to identify the presence of small particles so that the analyzer does not count them is referred to as the:
ackground count
. gglutinin zero point
hreshold control test
istogram output

amples from _____ may not be adequately evaluated with impedance analyzers as a result of the size similarities between red blood cells and platelets.
a. ogs
b. ats
orses
d. ows

6. hat is the volume of each of the nine squares of the hemo cytometer with the Neubauer ruling?

b.

hich term describes an increase in the number of circulat ing erythrocytes?
ancytopenia
b. ythropenia
eticulocytosis
olycythemia

hich of the following is a possible cause of relative polycythemia?
umors
b. ung disease
nic contraction
xcess EPO in the blood

hich of the following is a common cause of increased plasma protein levels?
Overhydration
. enal disease
ver disease
Dehydration

hich term describes plasma that appears to have a red tinge in a spun microhematocrit tube?
Icteric
. Hemolyzed
Lipemic
Polycythemic

hich term describes plasma that appears to have a yellow tinge in a spun microhematocrit tube?
Icteric
. Hemolyzed
Lipemic
Polycythemic

hich term describes plasma that appears milky in a spun microhematocrit tube?
Icteric
. Hemolyzed
Lipemic
Polycythemic

5. hich instrument is used to measure the total protein content of a sample?
mpedance counter
. HemoCue
Refractometer
Centrifuge

6. hich of the following causes a false decrease in packed cell volume?
rtened centrifuge time
. Icterus
ow blood-to-anticoagulant ratio
lots in the blood sample

he normal packed cell volume in dogs is about:

.

hat is the MCV in a canine patient with a PCV of 38% and a RBC count of 6.5

.
pg
pg

hat is the unit of measure for MCHC?

. pg

.

10. n estimate of the total red blood cell count can be obtained by dividing the _____ by 6.

.
emoglobin level

1. hen making a blood smear with a sample that is very thick and that contains some small clots, you should do which of the following?
ncrease the spreader slide angle to about 45 degrees.
. ecrease the spreader slide angle to about 20 degrees.
ilute the sample 2 ith EDTA.
ake the smear from a fresh sample.

2. hat is the predominant white blood cell type in ruminants?
Neutrophil
. Lymphocyte
Eosinophil
Monocyte

3. hich cell type is characterized by amoeboid nuclear mate rial and abundant, blue-gray, vacuolated cytoplasm?
Neutrophil
. Lymphocyte
Eosinophil
Monocyte

4. hich white blood cell is the predominant one that responds to allergies and parasitic disease?
   Neutrophil
   . Lymphocyte
   Eosinophil
   Monocyte
5. hich cell type can be identified by its dark, irregular, lobu lated nucleus and its colorless or pale-pink cytoplasm?
   Neutrophil
   . Lymphocyte
   Eosinophil
   Monocyte

he cell with a rounded or slightly indented nucleus that almost completely fills the cell is the mature _____.
   Neutrophil
   . Lymphocyte
   Eosinophil
   Monocyte

hich of the following best describes the granules of feline eosinophils?
   mall and round
   . arying size
   Rod-shaped
   e and oval

hich is the largest white blood cell in the peripheral blood?
   Neutrophil
   . Lymphocyte
   Eosinophil
   Monocyte

f a patient has 70% neutrophils on the differential blood cell film and a white blood cell count of 12,000, what is the absolute number of neutrophils present per

.

ocytosis is the primary function of which cell?
   Eosinophil
   . Lymphocyte
   Basophil
   Neutrophil

hich of the following best describes the morphology of canine erythrocytes?
   Elliptical
   . Nucleated
   iconcave disc
   Round

hich of the following best describes the morphology of avian erythrocytes?
   Elliptical
   . Nucleated
   iconcave disc
   Round

elet estimate that is performed with the use of a dif ferential blood cell film requires the counting of platelets in a minimum of _____ microscopic fields.

.

ultiply the platelet estimate obtained from the blood film by _____ to get the platelet estimate per L of blood.

.

hich of the following can be seen in lead poisoning?
   asophilic stippling
   . Spherocytosis
   Echinocytosis
   Anisocytosis

hich abnormality is characterized by grapelike clusters of red blood cells that do not break up when the sample is diluted with saline?
   owell-Jolly bodies
   . einz bodies
   Rouleaux
   Agglutination

hich red blood cell abnormality is often seen in healthy horses?
   owell-Jolly bodies
   . einz bodies
   Rouleaux
   Agglutination

hich term describes pale or bluish round areas attached to the red blood cell membrane that are caused by chemi cal- or drug-induced oxidative injury?
   owell-Jolly bodies
   . einz bodies
   Rouleaux
   Agglutination

hich abnormality is characterized by coinlike stacks of red blood cells?
   owell-Jolly bodies
   . einz bodies
   Rouleaux
   Agglutination

hich term describes round basophilic nuclear remnants in the red blood cells of animals with regenerative anemia?
   owell-Jolly bodies
   . einz bodies
   Rouleaux
   Agglutination

7. hich of the following is a toxic change that may be observed in neutrophils?
   odies
   . owell-Jolly bodies
   einz bodies
   uclear hyposegmentation

8. he presence of basophilic macrocytes on a peripheral blood cell film usually indicates increased numbers of:

Codocytes
. Reticulocytes
Metarubricytes
Dacrocytes

9. hich term describes cells with regular cytoplasmic projections around the periphery that give the cell the appearance of a scalloped border?
Acanthocytes
. Keratocytes
Echinocytes
Schistocytes

mall round or rod-shaped structures that are found as single organisms or pairs on the periphery of a red blood cell are:
einz bodies
. odies
c. *Ehrlichia*
d. *Mycoplasma*

hich type of stain is used to prepare a reticulocyte count

Supravital
. Romanowsky
Diff-Quik
Wright's

2. ow is the reticulocyte count recorded if a reticulocyte smear from a cat has 5 punctate reticulocytes and 15 aggregate reticulocytes per 1000 red blood cells?

.

3. ow is the reticulocyte count recorded if a reticulocyte smear from a dog has 25 reticulocytes per 1000 red blood cells?

.

4. hat is the absolute value of reticulocytes if 200 reticulocytes are counted per 1000 red blood cells and the total red blood cell count is 2.2

.

hat is the corrected reticulocyte percentage if a canine patient has 10% reticulocytes and a packed cell volume of

.

6. hat is the corrected reticulocyte percentage if a feline patient has 10% reticulocytes and a packed cell volume of 32%?

.

hat is the minimum number of nucleated cells that are counted and classified to calculate the ratio of myeloid cells to erythroid cells in bone marrow?

.

ow would a bone marrow sample from an adult animal be described if it contains 80% fat?
Aplastic
. Hypocellular
Hypercellular
Normal

ow would a bone marrow sample from a juvenile animal be described if contains 50% fat?
Aplastic
. Hypocellular
Hypercellular
Normal

hat stain is used to evaluate the presence of hemosiderin in a bone marrow sample?
Wright-Giemsa
. russian blue
Diff-Quik
Wright's

hat is the common term that is used to describe the presence of neoplastic blood cells in the bone marrow and the peripheral blood?
eukemia
ymphoproliferative
yeloproliferative
yogranulomatous

hich of the following is likely to cause microcytic anemia?
lichiosis
b. ug toxicity
ypothyroidism
ron deficiency

hich term describes chronic bone marrow inflammation that is characterized by increased numbers of macrophages?
ypoplastic
b. ranulomatous
yogranulomatous
rinous

hich term describes chronic bone marrow inflammation that is characterized by increased numbers of macrophages and neutrophils?
ypoplastic
b. ranulomatous
yogranulomatous
rinous

he classification of anemia according to _____ distinguishes between regenerative and nonregenerative anemia.

one marrow response
b. ythrocyte indices
tiology
orphology

hat is the molecule that platelets express on their surface when they are activated?
hrombin
b. on Willebrand factor
hatidylserine
icroparticles

2. hich molecule binds to tissue factor in the plasma to initiate the coagulation reactions?
actor VIII
b. hrombin
on Willebrand factor
rothrombin

hich of the following functions to stabilize the platelet plug?
actor VIII
b. hrombin
on Willebrand factor
rothrombin

4. hich factor is activated as a result of the formation of coagu lation complexes?
actor II
b. actor VIII
actor IX
d. ctor X

hich of the following is involved in the breakdown of the clot?
hrombin
b. issue factor
issue plasminogen activator
imers

hich anticoagulant is preferred for platelet testing?
eparin
b. odium citrate
A
mmonium oxalate

hich is the preferred anticoagulant for most plasma assays of coagulation?
eparin
b. odium citrate
A
mmonium oxalate

hat is the proper ratio of blood to citrate anticoagulant?

.

hat type of technology is used in the Coag Dx™ analyzer to evaluate coagulation?
detector
b. echanical
ire movement
ollagen-coated membrane

hat type of technology is used in the PFA-100 analyzer to evaluate coagulation?
detector
b. echanical
ire movement
ollagen-coated membrane

1. hich term describes the average size of the individual plate lets in a sample?
eletcrit
. ean platelet volume
elet–large cell ratio
elet distribution width

2. hich term refers to the percentage of the total blood volume that is comprised of platelets?
eletcrit
. ean platelet volume
elet–large cell ratio
elet distribution width

hich test evaluates the variability in the size of platelets?
eletcrit
. ean platelet volume
elet–large cell ratio
elet distribution width

hich test provides a measure of the percentage of platelets that are larger than normal?
eletcrit
. ean platelet volume
elet–large cell ratio
elet distribution width

hich term describes newly released platelets that contain high levels of RNA?
elet bands
b. ranulated platelets
A-rich platelets
eticulated platelets

1. hich coagulation test uses a tube containing diatomaceous earth?

b. leeding time
T
CT

hich coagulation test evaluates the extrinsic coagulation pathway?

b. leeding time

T
CT
hat are D-Dimer and FDP tests used to evaluate?
rimary (mechanical) hemostasis
. econdary (chemical) hemostasis
ertiary hemostasis
nticoagulant rodenticide toxicity
hat is the PIVKA test used to evaluate?
rimary (mechanical) hemostasis
. econdary (chemical) hemostasis
ertiary hemostasis
nticoagulant rodenticide toxicity
hich test represents a primary assay for the evaluation of platelet number and function?
elet estimate
. uccal mucosa bleeding time
ee–White bleeding time
lot retraction

hich coagulation assay is a good screening test for roden ticide ingestion?
ctivated partial thromboplastin time
b. rothrombin time
on Willebrand antigen assay
elet count

2. hat is the most common inherited coagulation disorder of domestic animals?
hrombocytopenia
b. emophilia
nticoagulant rodenticide toxicity
on Willebrand disease
hich term refers to the presence of pinpoint hemorrhage?
chymoses
b. etechia
urpura
pistaxis

4. hich of the following is often found on a blood smear from patients with DIC?
histocytes
b. s
olycythemia
yeloproliferation

5. eficient or defective production of which coagulation factor results in hemophilia A?
actor VII
b. hristmas factor
actor VIII
rothrombin
hat is the most common coagulation disorder of domestic

hrombocytopenia
b. emophilia
nticoagulant rodenticide toxicity
on Willebrand disease

7. hich of the following are the vitamin-K–dependent coagu lation factors?
actors I, VII, X, and XII
. actors II, VII, IX, and X
actors II, VIII, XI, and XII
actors IV, IX, X, and XX
hat is the primary site for the production of coagulation factors?
one marrow
b. en
ile duct

APPENDIX

The data on the following pages were compiled from a variety of sources, including personal notes, workshops, conference pre sentations, and the references listed at the end of each chapter. These values can be affected by a large number of factors, such as the test methods used, the type of equipment used, and the characteristics of the patient. Each laboratory should establish its own reference ranges for the methods used in that particular laboratory.

Hematology Reference Ranges

Coagulation Reference Ranges

Clinical Chemistry Reference Ranges

Urinalysis Reference Ranges

High-power field.

Blood Gas and Acid Base Measurements (Mean
Unanesthetized Dogs

	Mixed Venous Blood

From DiBartola SP: *base disorders in small animal practice*

Bacterial Pathogens of Veterinary Importance

The following table is a summary of characteristics of and dis eases produced by microbial pathogens seen in mammals and birds. A comprehensive bacteriology text should be consulted for additional characteristics used to identify these species defini tively and for additional information about less common species.

- Gram-negative
- Facultative

- Pus

- Identification/differentiation
  - Growth
  - CAMP
  - Esculin
  - Acid

  - Oxalase
  - Catalase
  - Urease

- Gram-positive,
- Non–spore-forming
- Poor

Organism	Primary Species Affected	Disease or Lesion	Characteristics
***Dichelobacter* Species**			

D. nodosus	Sheep, cattle, pigs, goats	Foot rot	• Gram-negative, pleomorphic, slightly curved bacilli
			• Anaerobic
			• Identification/differentiation
			  • Cellular morphology
			  • Colony characteristics
			  • Esculin hydrolysis test
			  • Acid production in carbohydrate substrates
			  • Indole production test

***Ehrlichia* Species**			

E. bovis	Cattle	See *Anaplasma bovis*	• Gram-negative, coccoid to ellipsoid forms
			• Located within cytoplasmic vacuoles of endothelium, myeloid cells, granulocytes, or thrombocytes
			• Identification/differentiation
			  • Demonstration of organisms on blood film
			  • Immunology

E. canis	Dogs, other canids	Monocytic ehrlichiosis	
E. chaffeensis	Dogs	Monocytic ehrlichiosis	
E. ewingii	Dogs	Granulocytic ehrlichiosis	
E. muris	Mice	Ehrlichiosis	
E. platys	Dogs	See *Anaplasma platys*	
E. ruminantium	Ruminants	Heartwater	
***Enterobacter* Species**			

E. aerogenes	Most mammals	Mastitis, neonatal septicemia, metritis, urinary tract infection, wound infection	• Gram-negative, motile bacilli
			• Identification/differentiation
			  • Colony characteristics
			  • Cellular morphology
			  • Citrate utilization test
			  • Hydrogen sulfide production
			  • Acid and gas production from lactose

E. cloacae	Birds		
***Eperythrozoon* Species**			
See *Mycoplasma*			
***Erysipelothrix* Species**			

E. rhusiopathiae	Cattle, pigs, sheep, turkeys	Diamond skin disease, arthritis, endocarditis	• Gram-positive, non–spore-forming bacilli
			• Facultative anaerobes
			• Nonmotile
			• Identification/differentiation
			  • Cellular morphology
			  • Colony characteristics
			  • Hemolysis pattern
			  • Catalase test
			  • Esculin hydrolysis test
			  • Acid production from carbohydrates
			  • Hydrogen sulfide production
			  • CAMP test
			  • Immunology (agglutination)

***Escherichia* Species**			

E. coli (numerous pathotypes)	Most vertebrates	Enteritis, septicemia, ruminant mastitis, canine pyometra, cystitis, calf scours	• Gram-negative bacilli
			• Most are motile
			• Identification/differentiation
			  • Cellular morphology
			  • Colony characteristics
			  • Hemolysis pattern
			  • Growth on MacConkey agar
			  • Catalase test
			  • Oxidase test
			  • Acid and gas production from glucose
			  • Hydrogen sulfide production
			  • Immunology (agglutination, ELISA, PCR)
			  • Histology

Organism	Primary Species Affected	Disease or Lesion	Characteristics
Francisella **Species**			

F. tularensis	Rabbits, most other mammals	Pneumonia, fever, lymphadenitis, ulcerative dermatitis	• Gram-negative coccobacilli
			• Identification/differentiation
			  • Cellular morphology with fluorescent antibody stain
			  • Immunology (agglutination, ELISA, antibody titer)
			  • Histology

Fusobacterium **Species**			

F. equinum	Horses	Lower respiratory tract disease	• Gram-negative, non–spore-forming fusiform bacilli
			• Identification/differentiation
			  • Cellular morphology
			  • Colony characteristics
			  • Hemolysis pattern
			  • Catalase test
			  • Nitrate reduction test
			  • Esculin hydrolysis test
			  • Fermentation of glucose
			  • Indole production test

F. necrophorum	Cattle, sheep, horses, pigs, rabbits	Foot rot, mastitis, liver abscess, metritis, calf diphtheria, thrush (equine), abortion, ulcerative stomatitis, "bull nose"	
F. nucleatum	Cattle, sheep	Abortion	
Haemobartonella **Species**			
H. canis	Dogs	See *Mycoplasma haemocanis*	
H. felis	Cats	See *Mycoplasma haemofelis*	
Haemophilus **Species**			

H. felis	Cats	Rhinitis, conjunctivitis	• Gram-negative, pleomorphic bacilli or coccobacilli
			• May form filaments
			• Nonmotile
			• Facultative anaerobes
			• Growth on chocolate agar
			• Identification/differentiation
			  • Catalase test
			  • Indole production test
			  • CAMP test
			  • Acid production in carbohydrate substrates
			  • Urease test
			  • Immunology (immunohistochemistry, PCR)

H. haemoglobinophilus	Dogs	Vaginitis, cystitis	
H. influenzaemurium	Rodents	Respiratory disease, ocular disease	
H. paragallinarum	Chickens	Infectious coryza	
H. parasuis	Pigs	Glasser's disease, meningitis, myositis, pneumonia, septicemia	
Helicobacter **Species**			

H. bilis	Mice	Hepatitis	• Gram-negative helical, curved, or unbranched bacilli
			• Motile
			• Microaerophilic
			• Identification/differentiation
			  • Colony characteristics
			  • Catalase test
			  • Oxidase test
			  • Urease test

H. canis	Dogs	Gastroenteritis	
H. cholecystus	Hamsters	Cholecystitis, pancreatitis	
H. felis	Cats, dogs	Gastritis	
H. hepaticus	Mice, rats	Hepatitis	
H. muridarum	Mice, rats	Gastritis	
H. mustelae	Ferrets	Gastritis	
H. nemestrinae	Macaques	Gastritis	
H. pullorum	Poultry	Gastroenteritis, hepatitis	
H. pylori	Monkeys, cats	Gastritis	
H. rappini	Mice, rats, dogs, sheep	Abortion	
Histophilus **Species**			

H. somni	Cattle	Bronchopneumonia, "honker syndrome," myocarditis, otitis, conjunctivitis, myelitis, vaginitis, orchitis, thromboembolic meningoencephalitis	• Gram-negative, nonmotile, pleomorphic bacilli
			• Capnophilic
			• Identification/differentiation
			  • Colony characteristics
			  • Hemolysis pattern
			  • Catalase test
			  • Oxidase test
			  • Nitrate reduction test
			  • Immunology

Organism	Primary Species Affected	Disease or Lesion	Characteristics
Klebsiella **Species**			

K. pneumoniae pneumoniae	Cattle, horses, sheep, dogs, birds	Metritis, mastitis, neonatal septicemia	• Gram-negative, nonmotile, encapsulated bacilli
			• Identification/differentiation
			  • Colony characteristics
			  • Cellular morphology
			  • Citrate utilization test
			  • Hydrogen sulfide production
			  • Acid and gas production from lactose
			  • Urease test
			  • Indole production test

K. oxytoca	Horses	Vaginitis, metritis, abortion, infertility	
Lawsonia **Species**			

L. intracellularis	Pigs, hamsters, cats, dogs, horses, ferrets	Proliferative enteritis, "wet tail," ileitis	• Gram-negative, curved intracellular body
			• Motile
			• Identification/differentiation
			  • Cellular morphology with silver staining
			  • Immunology (ELISA, immunofluorescence)

Leptospira **Species**			

L. bratislava	Horses, pigs	Abortion	• Spiral bacteria
			• Aerobic
			• Motile
			• Identification/differentiation
			  • Cellular morphology with dark field microscopy
			  • Immunology (agglutination, PCR, fluorescent antibody stain)

L. canicola	Cattle, pigs, dogs	Uremia, abortion	
L. grippotyphosa	Cattle, pigs, horses	Fever, jaundice, uremia	
L. hardjo	Cattle	Abortion, infertility	
L. icterohaemorrhagiae	Dogs, cattle, rats	Septicemia, abortion	
L. kennewicki	Horses	Abortion	
L. pomona	Pigs, cattle, horses	Abortion	
Listeria **Species**			

L. monocytogenes	Cattle, sheep, goats, horses, birds, dogs, rodents, pigs	Central nervous system infection, abortion, mastitis, septicemia	• Gram-positive, non–spore-forming bacilli
			• Facultative anaerobes
			• Motile
			• Identification/differentiation
			  • Cellular morphology
			  • Colony characteristics
			  • Hemolysis pattern
			  • Catalase test
			  • Esculin hydrolysis test
			  • Acid production from carbohydrates
			  • Hydrogen sulfide production
			  • CAMP test

Mannheimia **Species**			

M. haemolytica	Cattle, sheep	Pneumonia, septicemia, mastitis	• Gram-negative bacilli and coccobacilli
			• Nonmotile
			• Facultative anaerobes
			• Identification/differentiation
			  • Colony characteristics
			  • Hemolysis pattern
			  • Oxidase test
			  • Acid production from glucose
			  • Nitrate reduction test

M. granulomatis	Cattle	Panniculitis	
M. varigena	Cattle	Pneumonia, septicemia, mastitis	
Moraxella **Species**			

M. bovis	Cattle	Infectious keratoconjunctivitis	• Gram-negative coccobacilli
			• Nonmotile
			• Identification/differentiation
			  • Colony characteristics
			  • Growth on MacConkey agar
			  • Hemolysis pattern
			  • Oxidase test
			  • Catalase test
			  • Nitrate reduction test
			  • Immunology (fluorescent antibody stain, ELISA)

M. canis	Dogs	Bite-wound infections	
M. ovis	Small ruminants	Pinkeye	

Organism	Primary Species Affected	Disease or Lesion	Characteristics
Morganella Species			

M. morganii	Dogs	Otitis externa, cystitis	• Gram-negative bacilli
			• Identification/differentiation
			  • Colony characteristics
			  • Oxidase test
			  • Indole production test

Mycobacterium Species			

M. avium avium	Birds	Tuberculosis	• Gram-positive, non–spore-forming bacilli
			• Nonmotile
			• Aerobic
			• Acid fast
			• Identification/differentiation
			  • Colony characteristics
			  • Cellular morphology
			  • Intradermal skin test
			  • Carbohydrate utilization test

M. avium paratuberculosis	Ruminants	Johne's disease	
M. bovis	Ruminants, dogs, cats, pigs, goats, nonhuman primates	Tuberculosis	
M. fortuitum	Cattle, cats, dogs, pigs	Mastitis; joint, lung, and skin disease	
M. intracellularae	Pigs, cattle, nonhuman primates	Tuberculosis, granulomatous enteritis	
M. lepraemurium	Cats, rats	Leprosy	
M. porcinum	Pigs	Lymphadenitis	
M. smegmatis	Cattle, cats	Mastitis, ulcerative skin disease	
M. vaccae	Cattle	Skin disease	
M. xenopi	Cats, pigs	Nodular skin lesions, lymphadenitis	
Mycoplasma Species			
Nonhemotropic Mycoplasmas			

M. agalactiae	Goats, sheep	Contagious agalactia	• Identification/differentiation
			  • Colony characteristics
			  • Colony stain with Diene stain
			  • Urease test
			  • Immunology (immunodiffusion, immunofluorescent assay, agglutination, ELISA)

M. alkalescens	Cattle	Arthritis, mastitis	
M. bovigenitalium	Cattle	Infertility, mastitis	
M. bovis	Cattle	Arthritis, mastitis, pneumonia, abortion, abscesses, otitis media, genital infections	
M. bovoculi	Cattle	Conjunctivitis	
M. californicum	Cattle	Mastitis	
M. canadense	Cattle	Abortion, mastitis	
M. capricolum	Goats	Abortion, mastitis, septicemia, polyarthritis, pneumonia	
M. conjunctivae	Sheep	Infectious keratoconjunctivitis	
M. cynos	Dogs	Pneumonia	
M. dispar	Cattle	Respiratory disease	
M. felis	Cats, horses	Conjunctivitis, pneumonia	
M. gallisepticum	Chickens, turkeys	Airsacculitis, sinusitis	
M. gatae	Cats	Arthritis	
M. hyopneumoniae	Pigs	Pneumonia	
M. hyorhinis	Pigs	Polyarthritis	
M. meleagridis	Turkeys	Airsacculitis, skeletal abnormalities	
M. mycoides capri	Goats	Arthritis, mastitis, pleuropneumonia, septicemia	
M. mycoides mycoides	Cattle, goats, sheep	Pleuropneumonia, mastitis, septicemia, polyarthritis, pneumonia	
M. ovipneumoniae	Goats, sheep	Pleuropneumonia	
M. pulmonis	Rats, mice	Murine respiratory mycoplasmosis	
M. synoviae	Chickens, turkeys	Infectious synovitis	
Hemotropic Mycoplasmas			

M. haemocanis	Dogs	Haemobartonellosis	• Coccoid organisms
			• Obligate intracellular parasites
			• Attach to red blood cell surface
			• Identification/differentiation
			  • Cellular morphology
			  • Immunology (PCR)

M. haemofelis	Cats	Haemobartonellosis, feline infectious anemia	
M. haemomuris	Rats, mice	Haemobartonellosis	
M. ovis	Sheep, goats	Eperythrozoonosis	
M. suis	Pigs	Eperythrozoonosis	
M. wenyonii	Cattle	Eperythrozoonosis	

Organism	Primary Species Affected	Disease or Lesion	Characteristics
Neisseria **Species**			

N. canis	Dogs	Bite-wound infections	• Gram-negative coccobacilli
			• Nonmotile
			• Identification/differentiation
			  • Colony characteristics
			  • Hemolysis pattern
			  • Oxidase test
			  • Catalase test
			  • Acid production from carbohydrates

N. weaveri	Dogs	Bite-wound infections	
Neorickettsia **Species**			

N. helminthoeca	Dogs, other canids	"Salmon poisoning"	• Gram-negative, coccoid to ellipsoid forms
			• Located within cytoplasmic vacuoles of myeloid cells or enterocytes
			• Identification/differentiation
			  • Demonstration of organisms on blood film
			  • Immunology

N. risticii	Horses	Potomac horse fever, monocytic ehrlichiosis	
Nocardia **Species**			

N. asteroides	Dogs, cats, cattle, horses, pigs	Lymphadenitis, subcutaneous abscess, stomatitis, mastitis, pleuritis, peritonitis, abortion	• Gram-positive, pleomorphic, non–spore-forming bacilli
			• Nonmotile
			• Aerobic
			• Acid-fast
			• Identification/differentiation
			  • Colony characteristics
			  • Cellular morphology
			  • Nitrate reduction test
			  • Esculin hydrolysis test
			  • Urease test

N. brasiliensis	Horses	Pneumonia, pleuritis	
N. otitidiscaviarum	Cattle, guinea pigs	Ear infections, mastitis	
Pasteurella **Species**			

P. caballi	Horses	Respiratory infection, metritis	• Gram-negative bacilli and coccobacilli
			• Nonmotile
			• Aerobes
			• Identification/differentiation
			  • Colony characteristics
			  • Hemolysis pattern
			  • Growth on chocolate agar and MacConkey agar
			  • Catalase test
			  • Urease test
			  • Indole production test
			  • Oxidase test
			  • Acid and gas production from carbohydrates
			  • Nitrate reduction test

P. canis	Dogs	Puppy septicemia	
P. gallinarum	Chickens, turkeys	Fowl cholera, salpingitis	
P. haemolytica	Cattle, sheep	See *Mannheimia haemolytica*	
P. lymphangitidis	Cattle	Lymphangitis	
P. mairii	Pigs	Abortion, septicemia	
P. multocida	Ruminants, pigs, rodents, dogs, cats, cattle	Pneumonia, fowl cholera, rhinitis, mastitis, hemorrhagic septicemia, bite-wound infections	
P. pneumotropica	Rodents, rabbits	Pneumonia	
P. trehalosi	Sheep	Septicemia, pneumonia	
Porphyromonas **Species**			

P. levii	Cattle, most mammals	Bovine summer mastitis, pleuritis	• Non–spore-forming, pleomorphic bacilli
			• Nonmotile
			• Obligate anaerobes
			• Identification/differentiation
			  • Colony characteristics
			  • Hemolysis pattern
			  • Acid production on carbohydrate substrates
			  • Indole production test

P. gingivalis	Numerous	Periodontitis, gingivitis	

Organism	Primary Species Affected	Disease or Lesion	Characteristics
***Prevotella* Species**			

P. melaninogenica
P. heparinolytica
	Cattle
	Horses
		Foot rot
		Lower respiratory tract disease
			• Non–spore-forming, pleomorphic bacilli
			• Nonmotile
			• Obligate anaerobes
			• Identification/differentiation
			  • Colony characteristics
			  • Hemolysis pattern
			  • Acid production on carbohydrate substrates
			  • Indole production test

***Proteus* Species**			

P. mirabilis
P. vulgaris
	Dogs, horses, calves	Cystitis, pyelonephritis, prostatitis, otitis externa	• Gram-negative bacilli
			• Motile
			• Identification/differentiation
			  • Colony characteristics
			  • Oxidase test
			  • Hydrogen sulfide production
			  • Indole production test

***Pseudomonas* Species**			

P. aeruginosa
P. fluorescens
P. mallei
	Cattle, dogs, horses, sheep
	Cattle
		Mastitis, otitis externa, metritis, corneal ulcer, fleece rot
		Mastitis
		See *Burkholderia mallei*
			• Gram-negative, non–spore-forming bacilli
			• Aerobic
			• Identification/differentiation
			  • Colony characteristics
			  • Oxidase test
			  • Growth on MacConkey agar

***Rhodococcus* Species**			

R. equi	Horses, pigs	Bronchopneumonia, cervical lymphadenitis	• Gram-positive, pleomorphic coccobacillus
			• Aerobic
			• Partially acid-fast
			• Identification/differentiation
			  • Colony characteristics
			  • Catalase test
			  • Hemolysis pattern
			  • CAMP test
			  • Immunology (immunodiffusion, ELISA)

***Rickettsia* Species**			
R. felis *R. rickettsii* *R. typhi*	Cats Dogs Rats	Flea typhus Rocky Mountain spotted fever Murine typhus	• Intracellular coccobacilli • Located in endothelial cells and smooth muscle cells • Identification/differentiation • Immunology (fluorescent antibody tests, PCR)
***Salmonella* Species**			

S. ser. abortusovis
S. ser. anatum
S. ser. choleraesuis
S. ser. dublin
S. ser. enteritidis
S. ser. newport
S. ser. pullorum
S. ser. typhimurium
	Sheep
	Sheep, goats, horses
	Pigs
	Cattle, sheep, goats
	Horses
	Cattle
	Poultry
	Cattle, sheep, goats, horses, pigs
		Abortion
		Peracute septicemia; acute, subacute, or chronic enteritis
			• Gram-negative, non–spore-forming bacilli
			• Most are motile
			• Nearly 2500 serovars
			• Organisms are referred to by the genus name and serovar
			• Identification/differentiation
			  • Colony characteristics
			  • Growth on MacConkey agar
			  • Growth on Simmons citrate
			  • Urease test
			  • Indole production test
			  • Hydrogen sulfide production

Organism	Primary Species Affected	Disease or Lesion	Characteristics
Staphylococcus **Species**			
S. aureus	Mammals	Wound infections, mastitis, skin infections, vaginitis	• Gram-positive cocci • Aerobic
S. epidermidis	Cattle, other mammals	Mastitis, skin abscess	• Identification/differentiation • Colony characteristics • Hemolysis pattern • Catalase test • Coagulase test • Fermentation of sugars
S. felis	Cats	Otitis externa, cystitis, abscesses, wound infections	
S. intermedius	Dogs, cattle	Skin and ear infections, mastitis	
Streptococcus **Species**			
S. agalactiae	Cattle, horses	Mastitis	• Gram-positive, non–spore-forming cocci • Facultative anaerobes • Identification/differentiation • Colony characteristics • Hemolysis pattern • Catalase test • Esculin hydrolysis test • CAMP test • Fermentation of sugars
S. canis	Dogs, cats	Genital, skin, and wound infections; metritis, mastitis, kitten septicemia	
S. dysgalactiae dysgalactiae	Cattle, dogs	Mastitis, dermatitis, abortion, septicemia	
S. equi equi	Horses	Strangles, genital infection, mastitis	
S. zooepidemicus equi	Rats, cattle, goats, sheep, chickens	Mastitis, lymphadenitis, wound infections, pneumonia, septicemia	
S. porcinus	Pigs	Abscesses, lymphadenitis	
S. suis	Pigs	Encephalitis, meningitis, arthritis, septicemia, abortion, endocarditis	
Taylorella **Species**			
T. equigenitalis	Horses	Contagious equine metritis	• Gram-negative coccobacilli • Identification/differentiation • Colony characteristics • Growth on chocolate agar • Indole production test • Oxidase test • Catalase test • Esculin hydrolysis test • Immunology (PCR)
Treponema **Species**			
T. brennaborense	Cattle, horses	Digital dermatitis, "hairy foot warts"	• Tight spiral bacteria • Motile
T. paraluiscuniculi	Rabbits	Rabbit syphilis	• Identification/differentiation • Cellular morphology with silver staining
Ureaplasma **Species**			
U. diversum	Cattle	Abortion, vulvitis, pneumonia	• Small mycoplasmas • Identification/differentiation • Colony characteristics • Urea hydrolysis • Immunology (PCR, immunofluorescence assay)
Yersinia **Species**			
Y. enterocolitica	Rabbits, dogs, pigs, horses	Ileitis, gastroenteritis	• Gram-negative bacilli • Facultative anaerobes • Identification/differentiation • Cellular morphology • Colony characteristics • Oxidase test • Catalase test • Fermentation of sugars
Y. pestis	Dogs, cats, goats	Plague	
Y. pseudotuberculosis	Rodents, guinea pigs, cats, cattle, goats	Pseudotuberculosis, abortion, epididymitis, orchitis

APPENDIX E

Common Parasites of Some Exotic Animal Species

PARASITES OF BIRDS

Nematodes

Ascaridia species
Capillaria species
Dispharynx nasuta
Heterakis gallinarum
Spiroptera incesta
Tetrameres species

Trematodes

Schistosoma species

Protozoans

Aegyptianella species
Atoxoplasma serini
Cryptosporidium species
Eimeria species
Giardia species
Haemoproteus species
Histomonas meleagridis
Isospora species
Leucocytozoon species
Plasmodium species
Trichomonas gallinae
Trypanosoma species

Arthropods

Argas persicus
Cnemidocoptes mutans
Cnemidocoptes pilae
Dermanyssus gallinae
Echidnophaga gallinacea
Goniocotes gallinae
Haemaphysalis leporispalustris
Menacanthus stramineus
Ornithonyssus sylviarum

Annelids

Theromyzon tessulatum

PARASITES OF RABBITS

Nematodes

Obeliscoides cuniculi
Passalurus ambiguus
Trichostrongylus calcaratus

Protozoans

Eimeria irresidua
Eimeria magna
Eimeria media
Eimeria perforans
Eimeria stiedae

Arthropods

Cediopsylla simplex
Cheyletiella parasitivorax
Cuterebra species
Dermacentor variabilis
Haemaphysalis leporispalustris
Hemodipsus ventricosus
Listrophorus gibbus
Odontopsylla multispinosus
Psoroptes cuniculi
Sarcoptes scabiei

PARASITES OF GUINEA PIGS

Nematodes

Paraspidodera uncinata

Protozoans

Cryptosporidium wrairi
Eimeria caviae
Entamoeba caviae
Giardia caviae
Giardia muris
Tritrichomonas caviae

Arthropods

Chirodiscoides caviae
Dermacentor variabilis
Gliricola porcelli
Gyropus ovalis
Notoedres muris
Ornithonyssus bacoti
Sarcoptes scabiei
Trixacarus caviae

PARASITES OF RATS

Nematodes

Aspiculuris tetraptera
Syphacia muris

Syphacia obvelata
Trichosomoides crassicauda

Cestodes

Hymenolepis diminuta
Hymenolepis nana

Protozoans

Eimeria nieschultz
Giardia muris
Spironucleus muris
Tetratrichomonas microti
Tritrichomonas muris

Arthropods

Cuterebra species
Dermacentor variabilis
Notoedres muris
Ornithonyssus bacoti
Polyplax spinulosa
Radfordia ensifera

PARASITES OF MICE

Nematodes

Aspiculuris tetraptera
Syphacia muris
Syphacia obvelata

Cestodes

Hymenolepis diminuta
Hymenolepis nana

Protozoans

Eimeria falciformis
Eimeria ferrisi
Eimeria hansonorum
Eimeria hansorium
Giardia muris
Klossiella muris
Spironucleus muris
Tetratrichomonas microti
Tritrichomonas muris

Arthropods

Cuterebra species
Dermacentor variabilis
Myobia musculi
Myocoptes musculinus
Polyplax serrata
Ornithonyssus bacoti
Radfordia affinis
Radfordia ensifera

PARASITES OF HAMSTERS

Nematodes

Syphacia muris
Syphacia obvelata

Cestodes

Hymenolepis diminuta
Hymenolepis nana

Protozoans

Giardia species
Spironucleus muris
Tetranucleus microti
Tritrichomonas muris (criceti)

Arthropods

Demodex aurati
Demodex criceti
Ornithonyssus bacoti

PARASITES OF GERBILS

Nematodes

Dentostomella translucida

Cestodes

Hymenolepis diminuta
Hymenolepis nana

Arthropods

Demodex aurati
Demodex criceti
Hoplopleura meridionidis

PARASITES OF FISH

Protozoans

Chilodonella species
Cryptocaryon irritans
Ichthyophthirius multifiliis
Piscinoodinium species
Tetrahymena species

PARASITES OF REPTILES

Pentastomes

Armillifer species
Porocephalus crotali
Porocephalus species
Kiricephalus species

Example of a Standard Protocol for Reporting Results of a Urinalysis Laboratory Report

G APPENDIX

Taxonomic Classification of Parasites

Kingdom: Animalia (Animals)

- Phylum: Platyhelminthes (flatworms)
  - Class: Trematoda (flukes)
    - Subclass: Monogenea (monogenetic flukes)
    - Subclass: Digenea (digenetic flukes)
  - Class: Cotyloda (pseudotapeworms)
- Phylum: Nematoda (roundworms)
- Phylum: Acanthocephala (thorny-headed worms)
- Phylum: Arthropoda (animals with jointed legs)
  - Subphylum: Mandibulata (possess mandibulate mouthparts)
    - Class: Crustacea (aquatic crustaceans)
    - Class: Insecta
      - Order: Dictyoptera (cockroaches)
      - Order: Coleoptera (beetles)
      - Order: Lepidoptera (butterflies and moths)
      - Order: Hymenoptera (ants, bees, and wasps)
      - Order: Hemiptera (true bugs)
      - Order: Mallophaga (chewing or biting lice)
      - Order: Anoplura (sucking lice)
      - Order: Diptera (two-winged flies)
      - Order: Siphonaptera (fleas)
- Phylum: Sarcomastigophora
  - Subphylum: Mastigophora (flagellates)
- Phylum: Sarcomastigophora
  - Superclass: Sarcodina (amoebae)
- Phylum: Ciliophora (ciliates)
- Phylum: Apicomplexa (apicomplexans)
- Phylum: Proteobacteria
  - Class: Alpha Proteobacteria
    - Order: Rickettsiales
      - Family: *Rickettsiaceae*
      - Family: *Anaplasmataceae*

Zoonotic Internal Parasites

PARASITE	HOST	RESERVOIR	INFECTIVE STAGE	CONDITION
Toxocara spp.	Dogs, cats	Dogs, cats	Egg with L2	Visceral larva migrans
Ancylostoma spp.	Dogs, cats	Dogs, cats	L3	Cutaneous larva migrans
Uncinaria stenocephala	Dogs, cats	Dogs, cats	L3	Cutaneous larva migrans
Toxoplasma gondii	Cats	Cats, raw meat	Sporulated oocyst, bradyzoite, tachyzoite	Toxoplasmosis
Strongyloides stercoralis	Dogs, cats, people	People, dogs, cats	L3	Strongyloidiasis
Dipylidium caninum	Dogs, cats, people	Fleas	Cysticercoid	Cestodiasis
Taenia saginata	People	Bovine muscle	Cysticercus	Cestodiasis
Taenia solium	People	Porcine muscle, people	Cysticercus, egg	Cestodiasis, cysticercosis
Echinococcus granulosus	Dogs	Dogs	Egg	Hydatidosis
Echinococcus multilocularis	Dogs, cats	Dogs, cats	Egg	Hydatidosis
Spirometra mansonoides	Dogs, cats	Unknown	Procercoid in arthropod	Sparganosis
Sarcocystis spp.	People, dogs, cats	Cattle, pigs, dogs, cats	Sarcocyst in muscle, oocyst	Sarcocystiasis, sarcosporidiosis
Cryptosporidium	Mammals	Mammals	Oocyst	Cryptosporidiosis
Balantidium coli	People, pigs	People, pigs	Cyst, trophozoite	Balantidiasis
Ascaris suum	Pigs	Pigs	Eggs with L2	Visceral larva migrans
Trichinella spiralis	Mammals	Porcine and bear muscle	Encysted L3	Trichinellosis
Thelazia spp.	Mammals	Flies	L3	Verminous conjunctivitis
Giardia spp.	Mammals	Mammals	Cyst	Giardiasis
Babesia spp.	Rodents, people	Hard ticks	Sporozoite	Babesiosis
Trypanosoma cruzi	Mammals	Reduviids	Trypanosomal form in kissing bug	Chagas disease

From Sirois M: *Principles and practice of veterinary technology,* ed 3, St Louis, 2011, Mosby.

GLOSSARY

Abdominocentesis Paracentesis of the abdomen.

Absolute value The number of each type of leukocyte in peripheral blood; this is calculated by multiplying the relative percentage from the differential count by the total white blood cell count.

Acanthocyte An erythrocyte with spiny projections of varying lengths distributed irregularly over its surface.

Acariasis Infestation with mites.

Accuracy The closeness with which test results agree with the true quantitative value of the constituent.

Acid–base balance A state of equilibrium between the acidity and alkalinity of the body fluids; also called the hydrogen ion (H^+) balance.

Acid-fast stain A staining procedure for demonstrating the presence of microorganisms that are not readily decolorized by acid after staining; this is a characteristic of certain bacteria, particularly *Mycobacterium* and *Nocardia*.

Acidosis A pathologic decrease in the pH of blood or body tissues as a result of the accumulation of acids or a decrease in bicarbonate.

Acinar Pertaining to or affecting an acinus or acini. This term refers specifically to glandular tissue with a structure that is often described as grapelike clusters.

ACTH stimulation test A test designed to test the response of the hormone that stimulates adrenocortical growth and secretion.

Activated clotting time A test of the intrinsic and common pathways of blood coagulation that involves the use of a diatomaceous earth or kaolin tube to initiate clotting.

Activated partial thromboplastin time A test of intrinsic and common coagulation pathways. An intrinsic pathway activator is added to plasma, and the time taken for clot formation is measured.

Active immunity An animal's production of antibody as a result of infection with an antigen or immunization.

Acute-phase proteins Proteins, including serum amyloid A and C-reactive protein, that are produced by hepatocytes immediately following injury or inflammation.

Addison's disease See *Hypoadrenocorticism.*

Adrenocorticotropic hormone A hormone secreted by the anterior pituitary gland that has a stimulating effect on the adrenal cortex. Also referred to as corticotropin and abbreviated as ACTH.

Agar A seaweed extract that is used to solidify culture media.

Agranulocytes The white blood cell group that has no visible cytoplasmic granules.

Alanine transaminase Cytoplasmic enzyme of hepatocytes released when hepatocytes are damaged.

Albumin A group of plasma proteins that comprises the majority of protein in plasma.

Alkaline phosphatase A group of enzymes that functions at an alkaline pH and that catalyzes the reactions of organic phosphates.

Alkalosis A condition in which the blood pH is higher than 7.45.

Allantoin A crystalline substance produced by the oxidation of uric acid by uricase and present in the urine of most mammals, except primates and Dalmatian dogs (which lack uricase).

Alloantibodies A naturally occurring antibody that is produced by an individual and that reacts with antigens of another individual of the same species.

Alpha-hemolysis Characterized by the partial destruction of blood cells on blood agar, which is evident as a greenish zone around the bacterial colony.

Ammonium biurate Brownish crystals seen in the urine of animals with severe liver disease.

Amylase An enzyme derived primarily from the pancreas that functions in the breakdown of starch.

Amyloclastic A method of measuring serum amylase by evaluating the disappearance of starch substrate.

Anion A negatively charged ion.

Anion gap A method that is used to evaluate a patient's acid-base status; the calculation is based on subtracting the sum of measured major serum anions ($Cl^- + HCO_3^-$) from the sum of measured major serum cations ($Na^+ + K^+$).

Anisokaryosis Variation in the size of the nuclei of cells in a sample.

Anisonucleoliosis Variation in the size of nucleoli.

Antibody titer The level of a specific antibody that is present in serum. This is calculated as the reciprocal of the highest dilution at which a sample no longer exhibits a positive reaction for the presence of the antibody. It is often used to help differentiate active infection from prior exposure to an antigen.

Anticoagulant Any substance that inhibits or prevents clotting.

Antimicrobial disks Paper disks impregnated with antibiotic agents and used during the performance of the antimicrobial sensitivity test.

Antimicrobial susceptibility test An in vitro test of the effectiveness of selected antimicrobial agents against microorganisms.

Anuria Absence of urine.

Apoptosis The death of single cells by a process involving shrinkage, rapid fragmentation, and the engulfment of the fragments by neighboring cells and macrophages.

Arachnid A member of the class Arachnida, which includes mites and ticks.

Arthrocentesis The removal of fluid from a joint.

Ascarid Any of the nematodes of the superfamily Ascaridoidea, which includes the genera *Ascaris, Parascaris, Toxocara,* and *Toxascaris.*

Ascospores The sexual spore of *Ascomycetes.*

Aspartate transaminase An enzyme that is present in body serum and in certain body tissues that catalyzes the transfer of an amino group from aspartic acid to alpha-ketoglutaric acid, thereby forming glutamic acid and oxaloacetic acid. Also referred to as aspartate aminotransferase.

Aspiration The removal of fluids or gases from a cavity with the aid of suction; the removal of cells and tissue fluid from a lesion with the use of suction from a needle and syringe.

Atypical lymphocyte A general term used to describe a lymphocyte with morphologic abnormalities, including azurophilic granules, increased cytoplasmic basophilia, overly abundant cytoplasm, or a larger and more convoluted nucleus than seen in normal lymphocytes.

Autoagglutination The clumping or agglutination of an individual's cells by that individual's own serum, usually because of the presence of autoantibodies.

Avidity Refers to the strength of the binding of antigen and antibody.

Azotemia The increased retention of urea in the blood.

Bacilli Rod-shaped bacteria.

Baermann technique A parasitology test that is used to recover larvae.

Base excess The amount of acid or base required to titrate a sample of whole arterial blood to the normal pH of 7.4.

Basidiospores The sexual spore of basidiomycetes.

Basophil A granular leukocyte with an irregularly shaped, relatively pale-staining nucleus that is partially constricted into two lobes and with cytoplasm that contains coarse bluish-black granules of variable size.

Basophilic stippling Erythrocytes that are characterized by small, blue-staining granules; this represents the presence of residual RNA.

Beer's law A principle that describes the relationship between light absorbance, transmission, and the concentration of a substance in solution.

Bence Jones protein A light chain protein of immunoglobulin molecules that readily passes through the glomerulus and into the urine.

Benign A term used to describe a tumor or growth that is not malignant; this word can refer to any condition that is not life threatening.

Beta-hemolysis The complete destruction of red blood cells on blood agar that creates a clear zone around the bacterial colony.

Beta-lactamase Enzyme produced by bacteria that are resistant to beta-lactam antibiotics.

Bicarbonate (HCO_3) An electrolyte in plasma; part of the bicarbonate–carbonic acid buffer system that maintains the blood pH in equilibrium.

Bile acids A group of compounds that are synthesized by hepatocytes from cholesterol that help with fat absorption.

Bilirubin An insoluble pigment derived from the breakdown of hemoglobin, which is processed by hepatocytes.

Bilirubinuria An abnormal increase in the concentration of bilirubin in the urine.

Binocular Having two eyepieces (e.g., a type of microscope).

Biohazard Biological substances that contain infectious agents that pose a threat to human health.

Bladder expression The manual compression of the urinary bladder to cause the release of urine through the urethra.

Blood agar An enriched medium that supports the growth of most bacterial pathogens; usually composed of sheep's blood.

Blood group antigens The antigens that are present on the surface of erythrocytes and antibodies that may be present in serum.

Blood urea nitrogen The principal end product of amino acid breakdown in mammals.

Bloodborne pathogens Infectious agents that are present in the bloodstream.

Bothria Two longitudinal grooves or sucker-like expansions on the scolex of members of the cestode orders Bothriocephalidea, Diphyllidea, Diphyllobothriidea, and Trypanorhyncha.

Buccal mucosa bleeding time A test that uses a standardized shallow incision into the buccal mucosa of the upper lip to evaluate primary hemostasis.

Buffer A substance that increases the amount of acid or alkali necessary to produce a unit change in pH.

Buffy coat The layer of material above the packed erythrocytes after centrifugation; it consists primarily of leukocytes and thrombocytes.

Calcium The most abundant mineral in the body. Calcium is an important cation in intracellular and extracellular fluid. It is essential to the normal clotting of blood, the maintenance of a normal heartbeat, and the initiation of neuromuscular and metabolic activities.

Calcium carbonate A type of crystal that is commonly seen in the urine of rabbits and horses.

Calcium oxalate A crystal that is found in acidic and neutral urine; commonly seen in small amounts in dogs and horses.

California Mastitis Test An indirect test for bovine mastitis that is based on the presence of a high leukocyte count in mastitic milk.

Candle jar A method of producing anaerobic conditions for the growth of anaerobic bacteria.

Capnophilic An organism that requires high levels of carbon dioxide for growth or for the enhancement of growth.

Capsule stain A differential stain that is used to identify the cell capsules of pathogenic bacteria.

Carcinoma A term that describes tumors of epithelial cell origin.

Casts Structures that are formed from the protein precipitates of degenerating kidney tubule cells; may contain embedded materials.

Catalase An enzyme that catalyzes the breakdown of hydrogen peroxide into oxygen and water.

Catheterization The placement of a catheter in the urethra or the placement of an indwelling catheter in a blood vessel.

Cation A positively charged ion.

Cell-mediated immunity An immune system mechanism that involves actions of the cells of the immune system rather than antibodies.

Cellular cast A formed element in urine that consists of a hyaline cast that contains blood cells or epithelial cells.

Centesis The act of puncturing a body cavity or organ with a hollow needle to draw out fluid.

Centrifugal flotation A method of processing fecal samples for the detection of parasite ova and cysts. It recovers more eggs and cysts in a sample and takes less time than standard flotation.

Centrifuge A piece of equipment that spins samples at high speed.

Cercaria The life-cycle stage of trematodes that develops in the intermediate host.

Cestode An organism in the order Cestoda; a type of tapeworm.

Chemical hygiene plan A document that contains details about the specific chemical hazards present in the workplace.

Chemiluminescence Describes a chemical reaction that results in the emission of light.

Chloride The principal anion in extracellular fluid and gastric juice.

Cholesterol A plasma lipoprotein that is produced primarily in the liver as well as ingested in food; used in the synthesis of bile acids.

Citrate Any salt of citric acid; citrate salts are used as temporary anticoagulants for studies of blood coagulation.

Clot retraction A crude but simple test that allows for the evaluation of platelet number and function and intrinsic and extrinsic pathways.

Clumpelets A made-up word used to describe clumps of platelets seen on a blood smear.

Coagulase A molecule produced by some bacteria that allows for the adhesion of fibrinogen to the cell surface.

Cocci Bacteria with a round shape.

Codocyte An erythrocyte that is characterized by an increased membrane surface area relative to the cell's volume.

Competitive ELISA An immunoassay. Patient antigen, if present, competes with enzyme-labeled antigens for the antibodies that are coating the test wells.

Complement system A group of plasma proteins that function to enhance the activities of the immune system.

Compound light microscope A microscope that generates an image by using a combination of lenses.

Condenser The part of the microscope that consists of two lenses that focus light from the light source on the object being viewed. Light is focused by raising or lowering the condenser.

Conidia An asexual fungal spore that is deciduous (shed at maturity) and formed by budding or splitting off from the summit of a conidiophore. Also called a conidiospore.

Conjugated bilirubin Bilirubin that has been taken up by the liver cells and conjugated to form the water-soluble compound bilirubin diglucuronide.

Control A biological solution of known values that is used for the verification of the accuracy and precision of test results.

Coombs test An immunologic test designed to detect antibodies on the surface of erythrocytes (direct Coombs test) or antibodies against erythrocytes in plasma (indirect Coombs test).

Coracidium The individual free-swimming or free-crawling, spherical, ciliated embryo of tapeworms of the order Pseudophyllidea.

Cornified Keratinized; used to describe vaginal epithelial cells as seen in a vaginal cytology smear from a patient in estrus.

Cortisol A steroid hormone produced by the adrenal glands.

Coverslip smear A method of preparing a blood film with the use of two coverslips.

Creatine kinase An enzyme that is found predominantly in cells of the heart, brain, and skeletal muscle; released when cells are damaged.

Creatinine A waste product that is formed during normal muscle cell metabolism.

Crossmatching A blood test designed to identify compatibility between donor and recipient samples before transfusion.

Culture medium A substrate for the growth of microbiology samples.

Culturette The trade name for a sterile swab in transport media that is used for collection of microbiology samples.

Curschmann's spirals The coiled mucinous fibrils that are sometimes found in cytology preparations of bronchial samples.

Cushing's disease See *Hyperadrenocorticism.*

Cuticle The outer layer or covering of epithelium.

Cystine An amino acid that may be present in the form of hexagonal crystals in the urine.

Cystocentesis The aspiration of fluid from the urinary bladder.

D-Dimer A protein fragment that is formed from the breakdown of fibrin.

Dacryocyte An abnormal erythrocyte that is shaped like a teardrop.

Dark-field microscope A type of microscope that is used primarily in reference laboratories, especially for the viewing of unstained specimens.

Definitive host The host that harbors the adult, mature, or sexual stages of a parasite.

Dermatophyte test medium A differential culture medium designed to support the growth of cutaneous fungal organisms and to inhibit bacterial growth.

Dexamethasone suppression test An endocrine system test designed to detect hyperadrenocorticism.

Differential media A bacterial culture method that allows bacteria to be differentiated into groups on the basis of their biochemical reactions on the medium.

Dilution The process of making a solution weaker or less concentrated.

Direct life cycle The life cycle of an organism that does not require an intermediate host.

Direct sensitivity testing An antimicrobial sensitivity test that involves the application of undiluted samples (e.g., urine) directly to the Mueller-Hinton plate.

Discrete round cell tumors A neoplasia that is characterized by cells with discrete round shapes. Examples of round cell neoplasms include mast cell tumors, histiocytomas, lymphomas, plasmacytomas, and transmissible venereal tumors.

Disseminated intravascular coagulation An acquired secondary coagulation disorder that is characterized by the depletion of thrombocytes and coagulation factors. Also referred to as consumption coagulopathy and defibrination syndrome.

Dog erythrocyte antigen (DEA) A naming convention for canine blood types.

Döhle bodies Small, gray-blue areas that represent ribosomes and that are seen in the cytoplasm of some immature and toxic granulocytes.

Drepanocyte A morphologic abnormality of erythrocytes that is characterized by sickle-shaped cells.

Echinocyte An erythrocyte with multiple small projections that are evenly spaced over the cell circumference.

Ectoparasite A parasite that resides on the surface of its host.

Effective renal plasma flow The effective rate of blood flow through the kidneys; the determining factor relative to the rate of glomerular filtration.

Electrolyte Any substance that dissociates into ions when in solution.

End-point assay A chemical reaction that proceeds to a stable end point.

Endocrine A term that refers to the system of glands and other structures that secrete hormones directly into the circulatory system.

Endoparasite A parasite that resides within a host's tissues.

Endospore The dormant form of a bacterium; intracellular refractile bodies that are resistant to heat, desiccation, chemicals, and radiation; formed by some bacteria when environmental conditions are poor.

Endospore stain A differential stain that has been designed to identify the presence, location, and shape of spores in bacterial samples.

Engineering controls Safety procedures focused on changing the work environment to eliminate or minimize exposure to a hazard.

Enriched media A type of culture media that has been formulated to meet the requirements of the most fastidious pathogens.

Enterotubes A commercially available modular system of culture media that contains media and reagents for numerous bacteriologic tests that can be performed simultaneously.

Enzyme-linked immunosorbent assay (ELISA) An enzyme immunoassay that makes use of an enzyme-labeled immunoreactant (antigen or antibody) and an immunosorbent (antigen or antibody bound to a solid support).

Enzymuria The presence of specific enzymes in urine.

Eosin A type of pink to red acid dye that is a component of differential stains; primarily used for the routine staining of blood films.

Eosinophil A granulocyte with granules that have an affinity for the acidic components of stains.

Eosinophilic A term that refers to an increase in circulating eosinophils or a reddish appearance of cells or components of cells that have a high affinity for stains with acid pH.

Epithelial cell tumors A type of neoplasm associated with a clustered arrangement of cells into ball shapes or monolayer sheets. Examples include lung adenocarcinoma, perianal adenoma, basal cell tumor, sebaceous adenoma, transitional cell carcinoma, and mesothelioma.

Eryptosis The suicidal death of erythrocytes; similar to the apoptosis of nucleated cells.

Erythrocyte indices Calculated values that provide the average volume and hemoglobin concentrations of erythrocytes in a peripheral blood sample.

Erythropoiesis The production of erythrocytes.

Erythropoietin The hormone that stimulates erythropoietic activity in the bone marrow.

Ethylene glycol A solvent with a sweet, acrid taste that is found in many products, such as antifreeze, drying agents, and inks. Ingestion or excessive skin exposure can be toxic.

Ethylenediaminetetraacetic acid An anticoagulant that binds calcium.

Exudate A fluid accumulation that results from inflammatory processes; characterized by increased cellularity and protein concentration.

Facultative anaerobes Bacteria that do not require oxygen for metabolism but that can survive in the presence of oxygen.

Fastidious A term used to describe a bacterial species with complex growth or nutritional requirements.

Fatty casts Formed elements that may be found in urine and that consist of a hyaline cast with embedded globules of fat.

Fecal sedimentation A procedure that is used to prepare samples for examination for parasites; it demonstrates objects that are too heavy or too delicate to evaluate with standard fecal flotation.

Fibrin degradation products Protein fragments formed from the breakdown of fibrin.

Fibrometer An instrument used for the hemostatic evaluation of samples.

Fine-needle biopsy A sample collection method in which tissue is obtained by puncture of a lesion.

Flagella Long, thin, helical structures that function in cell motility.

Flagella stain A differential stain to detect and characterize flagella if present on bacterial cells.

Flea-bite dermatitis The inflammatory lesions and self-trauma caused by a hypersensitivity to flea bites.

Fluorescent antibody A specific antibody that has been labeled with a fluorochrome and that is used in immunoassays.

Fluorescent microscope A type of microscope that is capable of viewing fluorescent particles, such as an antibody labeled with specific fluorescent dye.

Fractional clearance of electrolytes A mathematical manipulation that describes the excretion of specific electrolytes relative to the glomerular filtration rate.

Free catch A method of collecting a urine sample by collecting the sample as the animal voids naturally.

Fructosamine A molecule formed as a result of the irreversible reaction of glucose bound to protein.

Gamma-glutamyltransferase An intracellular enzyme found in high concentrations in liver, pancreatic, and renal tubular cells.

Gamma-hemolysis A term that describes a bacterial sample that produces no hemolysis on blood agar.

Giemsa stain A differential stain that is used for blood and bone marrow smears. Also used to visualize fungal organisms and mast cell granules.

Globulins A complex group of plasma proteins that have been designated as alpha, beta, or gamma; this group includes immunoglobulins, complement, and transferrin.

Glomerular filtration rate The rate at which substances are filtered through the glomerulus and excreted in the urine.

Glomerulus A tuft of capillaries located in the renal cortex.

Glucagon A hormone secreted by the alpha cells of the islets of Langerhans in response to hypoglycemia.

Glucose A monosaccharide that represents the end product of carbohydrate metabolism.

Glucose tolerance test A metabolic test of carbohydrate tolerance.

Glucosuria The presence of glucose in the urine.

Glutamate dehydrogenase A mitochondrial-bound enzyme that is found in high concentrations in the hepatocytes of cattle, sheep, and goats.

Glycosylated hemoglobin The irreversible reaction of hemoglobin bound to glucose.

Gram stain A differential stain that is used to classify bacterial samples on the basis of the chemical structure of their cell walls.

Granular casts A structure that is formed from the protein precipitate of degenerating kidney tubule cells that contain granular material derived from the breakdown of cells incorporated into the cast.

Granulocytes Any cell with distinct cytoplasmic granules.

Granulomatous A term that refers to an inflammatory condition that is characterized by high numbers (more than 70%) of macrophages.

Hanging drop A method of preparing specimens to evaluate motility.

Heinz bodies Round structures of erythrocytes that represent denatured hemoglobin and that appear as a pale area when stained with Wright's stain.

Hematochezia The presence of blood in the feces.

Hematopoiesis The production of blood cells and platelets.

Hematuria The presence of intact erythrocytes in the urine.

Hemoglobin The oxygen-carrying pigment of erythrocytes, which is formed by developing erythrocytes in the bone marrow. It is a type of hemoprotein that contains four heme groups and globin.

Hemoglobinuria The presence of free hemoglobin in urine.

Hemolysis The destruction of erythrocytes.

Hemolyzed Red appearance of a fluid sample (e.g., serum, urine) as a result of the destruction of erythrocytes.

Hemophilia A genetic abnormality of hemostasis that results from the deficient production of certain coagulation factors.

Heparin An acid mucopolysaccharide that is present in many tissues, especially the liver and lungs, and that has potent anticoagulant properties.

Hepatoencephalopathy Severe hepatic insufficiency that may induce a syndrome of excitability, tremor, compulsive walking, head pressing, and apparent blindness, followed by coma and convulsions.

Heterophil A leukocyte of avian, reptile, and some fish species that contains prominent eosinophilic granules; functionally equivalent to the mammalian neutrophil.

Hexacanth The infective stage of some cestodes.

Histiocytoma A tumor that contains histiocytes (macrophages).

Histogram A graphic display of a frequency distribution that is represented by a series of rectangles that divide the data into classes. The height of a rectangle indicates the number of values that are contained in that class (class frequency), and the width of each base represents the size of the intervals into which the classes have been divided.

Howell-Jolly bodies Basophilic inclusions of young erythrocytes that represent nuclear remnants.

Humoral immunity An immune response that involves the production of specific antibody.

Hyaline casts The structures that are formed from protein precipitates of degenerating kidney tubule cells with no embedded materials.

Hyperadrenocorticism The abnormally increased secretion of adrenocortical hormones, as with conditions such as Cushing's syndrome.

Hypercalcemia An increased plasma calcium level.

Hypercapnia An excess of carbon dioxide in the blood that is indicated by an elevated PCO_2 level as determined by blood gas analysis and that results in respiratory acidosis. Also known as hypercarbia or hypercarbemia.

Hyperchromatophilic A term that refers to a cell that appears darker than normal on a peripheral blood sample.

Hypercoagulable Characterized by abnormally increased coagulability.

Hyperglycemia An abnormally increased glucose level in the blood.

Hyperkalemia An increased plasma potassium level.

Hyperlipoproteinemia A condition characterized by excess lipids in the blood. Also referred to as hyperlipidemia and hyperlipemia.

Hypernatremia An increased plasma sodium level.

Hyperphosphatemia An excessive amount of phosphates in the blood.

Hyperproteinemia An increased protein level in the blood.

Hypersegmentation A term that refers to a neutrophil with more than five nuclear lobes.

Hyperthyroidism A condition that is caused by the excessive production of iodinated thyroid hormones.

Hyphae The body of a fungus that is created as a result of the linear arrangements of cells and that forms multicellular or multinucleate growth.

Hypoadrenocorticism A deficiency in the production of mineralocorticoid or glucocorticoid steroid hormones.

Hypoalbuminemia A decrease in the circulating levels of albumin in the blood.

Hypocalcemia A decreased plasma calcium level.

Hypocapnia A deficiency of carbon dioxide in the blood. Also called hypocarbia.

Hypochromasia The presence of erythrocytes with decreased staining intensity as a result of a decrease in hemoglobin concentration.

Hypocoagulable Characterized by abnormally decreased coagulability.

Hypoglycemia A decreased plasma glucose level.

Hypokalemia A decreased plasma potassium level.

Hyponatremia A decreased plasma sodium level.

Hypophosphatemia A decreased amount of phosphates in the blood.

Hypoproteinemia A condition characterized by an abnormally low level of protein in the blood.

Hyposegmentation A term that is used to describe the nucleus of a leukocyte with fewer than the normal number of nuclear lobes.

Hypostome The penetrating, anchor-like sucking organ of the tick.

Icterus Abnormal yellowish discoloration of skin, mucous membranes, or plasma as a result of an increased concentration of bile pigments.

Iditol dehydrogenase An enzyme of the oxidoreductase class that catalyzes the oxidation of l-iditol to l-fructose; it occurs in significant quantities only in the liver, and its increased activity in serum is used as an indicator of parenchymal liver damage. Also referred to as sorbitol dehydrogenase.

Immunodiffusion An immunologic test that is performed by placing reactants in an agar plate and allowing them to migrate through the gel toward each other.

Immunoglobulins Antibodies; plasma proteins produced against specific antigens.

Immunologic tolerance A state of nonresponsiveness to antigens, whether self or foreign.

Impedance analyzer A type of analyzer that counts particles based on their displacement of electrolyte solution when the particles pass through an aperture. The magnitude of the displacement creates an electrical signal that allows particles (e.g., cells) to be classified on the basis of their size.

Incubator A piece of equipment that is used to maintain a constant and suitable temperature for the development of cultures of microorganisms or other living cells.

Indirect cycle The life cycle of an organism that requires one or more intermediate hosts.

Indirect sensitivity testing An antimicrobial sensitivity test that involves the application of diluted samples (e.g., urine) directly to the Mueller-Hinton plate.

Inflammatory response The defensive response of body tissues that is initiated by the release of histamine from damaged cells.

Instar Any stage of an arthropod between molts.

Insulin A protein hormone that is secreted by the beta cells of the pancreatic islets in response to elevated blood levels of glucose and amino acids.

Interferons Small soluble proteins that enhance the function of the immune system.

Intermediate host The host that harbors the larval, immature, or asexual stages of a parasite.

International units The Système International (SI) set of basic units, which is based on the metric system.

Jaundice A condition that is characterized by hyperbilirubinemia and the deposition of bile pigments in the skin, mucous membranes, and sclera.

Karyolysis The degeneration or dissolution of a cell nucleus.

Karyorrhexis The fragmentation of a cell nucleus.

Keratocyte In hematology, an abnormally shaped erythrocyte that appears to have horns.

Ketonuria The presence of detectable ketone bodies in urine.

Kinetic assay A chemical test that measures the rate of change of a substance in the test system.

Kirby-Bauer test A type of antimicrobial susceptibility test in which agar plates are inoculated with a standardized suspension of a microorganism, and then antibiotic-containing disks are applied to the agar surface.

Kovac's reagent A substance used in bacteriology to detect the ability of bacteria to produce indole.

Lactate The anionic form of lactic acid; a salt of lactic acid.

Lactophenol cotton blue A preparation of phenol, lactic acid, glycerin, distilled water, and cotton blue dye that is used to stain fungi in wet preparations.

Left shift The presence of increased numbers of immature cells in a peripheral blood sample.

Leptocyte An erythrocyte that is characterized by an increased membrane surface area relative to the cell volume.

Leukemia A condition characterized by the presence of neoplastic cells in the blood or bone marrow.

Leukemoid response The exhibition of blood counts (particularly leukocytosis) and sometimes other clinical findings that resemble those of leukemia.

Leukocytosis The presence of increased numbers of leukocytes in the blood.

Leukopoiesis The production of leukocytes.

Lipase A pancreatic enzyme that functions in the breakdown of fats.

Lipemia The presence of fatty material in plasma or serum.

Lymphocyte A leukocyte that is involved in the inflammatory process and that also has roles in humoral and cell-mediated immunity.

Lymphoma A neoplastic disorder of the lymphoid tissue.

Lymphopenia The presence of decreased numbers of leukocytes in a peripheral blood sample.

MacConkey agar An agar medium that contains peptone, lactose bile salts, sodium chloride, neutral red, and crystal violet that is used to differentiate lactose fermenters (coliforms) from non–lactose fermenters among the enteric bacilli.

Macrocytosis A condition in which a cell is abnormally large.

Mast cell tumors A benign local aggregation of mast cells that forms a nodular tumor that occurs in the skin of most species (most commonly dogs).

Material Safety Data Sheet (MSDS) Informational material that contains detailed product safety information about hazardous materials found in a particular place of a business; an OSHA mandate.

Mean corpuscular hemoglobin (MCH) An expression of the average hemoglobin content of a single cell in picograms that is obtained by multiplying the amount of hemoglobin (in

grams) by 10 and then dividing that number by the number of erythrocytes (in millions).

Mean corpuscular volume An expression of the average volume of individual red cells in cubic microns that is obtained by multiplying the hematocrit percentage by 10 and then dividing that number by the number of erythrocytes (in millions).

Megakaryocyte The bone marrow cell from which blood platelets arise.

Megathrombocytes Abnormally large platelets that are usually newly formed; seen in greater numbers during an increase in platelet production.

Melanoma A tumor that arises from melanocytes of the skin or other organs.

Mesenchymal cell tumors Tumors of mixed mesenchymal tissues with two or more cellular elements that are not commonly associated (not counting fibrous tissue as one of the elements).

Mesophiles Organisms with optimal growth temperatures of between 25° C and 40° C.

Metacercaria The encysted resting or maturing stage of a trematode parasite in the tissues of an intermediate host or on vegetation.

Methanol Methyl alcohol.

Methemoglobin The form of hemoglobin that contains oxidized iron; inefficient at oxygen transport.

Microaerophilic An organism that requires oxygen for growth at a level that is less than that found in air.

Microcytosis A cell that appears much smaller than normal.

Microfilaria The larval offspring of the group of filarial worms in the phylum Nematoda.

Microhematocrit A term that refers to use of a capillary tube and a high-speed centrifuge to determine the packed cell volume.

Minimum inhibitory concentration The smallest concentration of an antibiotic that regularly inhibits the growth of a bacterium in vitro.

Miracidium The ciliated larval stage of a digenetic trematode.

Modified transudate A transudate with additional protein, cells, or both; it may be a transitional stage that ultimately progresses into an exudate.

Monocyte A precursor cell representing a stage in the development of the tissue macrophage; after a monocyte leaves the bloodstream and enters tissue at a site of inflammation, it becomes an activated macrophage.

Mucin clot test The adding of acetic acid to normal synovial fluid, which causes clot formation; the compactness of the clot and the clarity of the supernatant fluid are the criteria on which the result is based.

Mueller-Hinton medium A standard culture material that is used to evaluate the susceptibility of microorganisms to antimicrobial agents.

Myiasis An infestation with the larvae (maggots) of dipterans.

Natural killer (NK) cells A subpopulation of lymphocytes that is capable of the direct lysis of cells that have been infected with antigen.

Nematode A multicellular parasitic animal of the phylum Nematoda.

Neonatal isoerythrolysis Hemolytic anemia of the newborn.

Neoplasia A generic term that is used to describe any growth; often used to describe a tumor, which may be malignant or benign.

Nephron A structural and functional unit of the kidney that resembles a microscopic funnel with a long stem and two convoluted tubular sections.

Neubauer rulings A specific pattern of precise markings on a hematocytometer slide that facilitates the counting of leukocytes, erythrocytes, and platelets in the blood and of all cells in other fluids.

Neutrophil A leukocyte that functions to phagocytize infectious agents and cellular debris; plays a major role in the inflammatory process.

Neutrophilia An abnormal increase in the number of neutrophils seen in a peripheral blood sample.

Nits The egg stage of lice, which binds to the hair or feather shaft of the host.

Nuclear molding A deformation of nuclei by other nuclei within the same cell or adjacent cells.

Nucleated erythrocyte An immature red blood cell that still contains a nucleus.

Numerical aperture A measure of the efficiency of a microscope objective lens; it is proportional to the square root of the amount of light that enters the instrument.

Nymph A developmental stage of certain arthropods between the larval form and the adult; resembles the latter in appearance.

Objective lens A lens that accepts light from the output phosphor of an image intensifier tube and converts it into a parallel beam to record the image on film.

Obligate anaerobes Organisms that cannot grow in the presence of oxygen.

Occupational Safety and Health Administration (OSHA) A U.S. government agency that mandates specific laboratory practices that must be incorporated into a laboratory's safety policy.

Ocular Pertaining to the eye.

Oliguria A decrease in the volume of urine produced.

Opsonization The complement-mediated adherence of phagocytes to antigens that enhances the phagocytosis of the antigen.

Optical density The degree to which light is transmitted through a medium.

Oxalate An anion of oxalic acid.

Oxidase An enzyme that is present in some groups of bacteria and that is involved with the reduction of oxygen during normal bacteria metabolism.

Packed cell volume The ratio of red blood cells to total plasma volume.

Paracentesis The removal of fluid from a body cavity.

Parthenogenetic A condition in which female organisms produce eggs that develop without fertilization.

Passive immunity A condition that involves receiving antibodies from colostrum or synthesized antibodies.

Pediculosis The term used to describe an infestation with lice.

Pelger-Huët anomaly An inherited anomaly that is characterized by the appearance of bilobed neutrophils in a peripheral blood sample.

Periodic parasite A parasite that lives part of its life cycle on its host and part of its life off of its host.

Peritoneal fluid A naturally produced fluid in the abdominal cavity that lubricates surfaces, thereby preventing friction between the peritoneal membrane and the internal organs.

Personal protective equipment Items such as eye protection and other protective clothing, shields, and barriers that are designed to minimize exposure to hazards in the workplace.

pH A measure of the hydrogen ion concentration of a solution.

Phase-contrast microscope A type of light microscope that involves a special condenser and objective lens with a phase-shifting ring; it is used to visualize small differences in refractive index as differences in intensity or contrast.

Pipette A calibrated, transparent, open-ended tube made out of glass or plastic that is used to measure or transfer small quantities of a liquid or gas. This word can also be used to refer to the use of a pipette to dispense liquid.

PIVKA Proteins induced by vitamin K deficiency or antagonists; the nonfunctional precursor forms of vitamin-K–dependent coagulation factors.

Plasma The fluid portion of the blood.

Plasma cell tumor An extramedullary myeloma; this type of tumor occurs outside of the bone marrow, and it usually affects the visceral organs or the nasopharyngeal and oral mucosa.

Platelets Irregular, disc-shaped fragments of megakaryocytes in the blood that assist with blood clotting.

Pleomorphism A term that refers to something that takes a variety of shapes and forms or that has multiple morphologies.

Plumbism A chronic form of lead poisoning that is caused by the absorption of lead or lead salts.

Pluripotent stem cell A cell capable of differentiating into one of many cell types.

Poikilocytosis Any abnormal cell shape.

Polymerase chain reaction A method that is used to replicate and amplify DNA molecules in a sample.

Polyuria An increase in the total volume of urine produced.

Precision The magnitude of random errors and the reproducibility of measurements.

Prepatent period The time interval between infection with a parasite and the demonstration of that infection.

Proglottid A segment that comprises the body of a cestode.

Proteinuria The abnormal presence of protein in the urine.

Prothrombin time tests A one-stage test for detecting certain plasma coagulation defects that are caused by a deficiency of factors V, VII, or X.

Psychrophiles Organisms that demonstrate optimal growth at cold temperatures (i.e., between 15° C and 20° C).

Punch biopsy The removal of living tissue for microscopic examination with the use of a punch.

Pupa The second stage in the life cycle of certain insects, which occurs between the larval and adult stages. A pupa shows the basic external features

of the adult form, but it does not have expanded wings.

Pyknosis The presence of condensed nuclear chromatin in a degenerating cell.

Pyogranulomatous A term used to describe a cytology sample that is characterized by the presence of macrophages representing more than 15% of total nucleated cells in the sample.

Quadrant streak A technique for microbial inoculation in which a single colony is isolated on a culture plate and divided into four sections.

Quality assurance Any evaluation of services provided and the results achieved as compared with accepted standards.

Radioimmunoassay A technique that is used to determine the concentration of an antigen, antibody, or other protein in the serum. A radioactively labeled substance that is known to react in a certain way with the suspected protein is injected, and any reaction is monitored.

Ratio The relationship of one quantity to one or more other quantities that is expressed as a proportion of one to the others and written either as a fraction or linearly.

Redia A secondary larval form of some digenetic trematodes that develops within a mollusk intermediate host.

Refractive index A measure of the degree that light bends as it passes from one medium to another.

Refractometer A device that measures the refractive index of a solution.

Reliability The ability of a method to be accurate and precise.

Resolution The ability of an imaging process to distinguish adjacent structures in the object; an important measure of image quality.

Rhizoid Resembling a root or serving to anchor.

Ringworm A group of fungal skin diseases that are caused by dermatophytes of several kinds.

Rostellum The anterior of a tapeworm scolex, which commonly features hooklike jaws.

Rouleaux An arrangement of erythrocytes that appears as a column or stack.

Sarcoma A generic term that is used to describe any cancer that arises from cells of the connective tissues.

Schistocytes Fragmented erythrocytes that are usually formed as a result of shearing of the red cell by intravascular trauma.

Scolex The anterior portion of a cestode by which it attaches to its host.

Selective media A type of culture media that contains antibacterial substances that inhibit or kill all but a few types of bacteria.

Serial dilution A laboratory technique in which a substance (e.g., serum) is decreased in concentration in a series of proportional amounts.

Serum The fluid portion of blood after it has clotted; it does not contain cells or coagulation proteins.

Smudge cell A leukocyte that has ruptured.

Specificity The ability of a test to evaluate a given parameter correctly.

Spectrophotometer A piece of equipment designed to measure the amount of light that is transmitted through a solution.

Spherocyte An intensely stained erythrocyte that has reduced or no central pallor.

Spirochete Any bacterium of the genus *Spirochaeta* that is motile and spiral-shaped, with flexible filaments.

Sporocyst The larval stage of a digenetic trematode that develops in a mollusk intermediate host.

Standard solution A nonbiological solution of an analyte, usually in distilled water, with a known concentration.

Stomatocyte An erythrocyte with a linear area of central pallor.

Struvite A common crystal that is seen in alkaline to slightly acidic urine. Also referred to as triple phosphate crystals or magnesium ammonium phosphate crystals.

Sulfhemoglobin A form of hemoglobin that is found in the blood in trace amounts and that contains an irreversibly bound sulfur molecule that prevents normal oxygen binding.

Supernatant The fluid portion of a sample that is present after centrifugation.

Suppurative Containing, discharging, or causing the production of pus; cytology sample characterized by the presence of neutrophils representing more than 85% of total nucleated cells in the sample. May also be described as purulent.

Synovial fluid A transparent, viscous fluid that is secreted by synovial membranes and that acts as a lubricant for many joints, bursae, and tendons. It contains mucin, albumin, fat, and mineral salts.

Target cell A leptocyte with a peripheral ring of cytoplasm surrounded by a clear area and a dense, central, rounded area of pigment.

Thermophiles Organisms that undergo optimal growth at elevated temperatures.

Thoracocentesis The removal of fluid from the thoracic cavity.

Thrombin An enzyme that is formed from prothrombin, calcium, and thromboplastin in plasma during the clotting process. Thrombin causes fibrinogen to change to fibrin, which is essential during the formation of a clot.

Thrombocytes Platelets; cytoplasmic fragments of bone marrow megakaryocytes.

Thrombocytopenia A condition that involves a decrease in the number of circulating platelets.

Thrombocytosis A condition that involves an increase in the number of circulating platelets.

Thrombopathia A condition in which there is a deficiency of clotting ability for reasons other than thrombocytopenia.

Thrombopoiesis The production of platelets.

Thyroid-stimulating hormone A substance secreted by the anterior lobe of the pituitary gland that controls the release of thyroid hormone and that is necessary for the growth and function of the thyroid gland.

Thyroxine A hormone of the thyroid gland that is derived from tyrosine and that influences the metabolic rate.

Tick paralysis A condition that results from the introduction of a neurotoxin into the body during the attachment of and feeding by the female of several tick species.

Transudate An effusion that is characterized by a low protein concentration and a low total nucleated cell count.

Trematode An organism in the phylum Trematoda; commonly referred to as a fluke.

Trypsin A proteolytic digestive enzyme that is produced by the exocrine pancreas and that catalyzes the breakdown of dietary proteins into peptones, peptides, and amino acids in the small intestine.

Trypsinogen The inactive precursor form of trypsin; it is secreted in pancreatic juice and converted into active trypsin through the action of enterokinase in the intestine.

Tyrosine An amino acid that is synthesized in the body from the essential amino acid phenylalanine; it is found in most proteins and is a precursor of melanin and several hormones, including epinephrine and thyroxin.

Undulate To have wavelike fluctuations or oscillations.

Uric acid A metabolic by-product of nitrogen catabolism.

Vaccination Any injection of attenuated microorganisms (e.g., bacteria, viruses, rickettsiae) that is administered to induce immunity or to reduce the effects of associated infectious diseases.

Vacutainer A glass tube with a rubber stopper from which air can be removed to create a vacuum; usually used to draw blood.

Veterinary technician A tireless, dedicated, and vital member of the veterinary health care team. Also referred to as a superhero or saint.

von Willebrand disease An inherited disorder that is characterized by the abnormally slow coagulation of the blood as well as spontaneous epistaxis and gingival bleeding. It is caused by a deficiency of a component of factor VIII. Excessive bleeding is common after injury or surgery.

Warbles The common name for the larva of some species of flies; they are often in swollen, cyst-like subcutaneous sites, with a fistula or pore that communicates with the outside environment.

Wood's lamp An illuminating device with a nickel oxide filter that holds back all light except for a few violet rays of the visible spectrum and ultraviolet wavelengths of about 365 nm. It is used extensively to help diagnose fungal infections.

Yeast Any unicellular (usually oval) nucleated fungus that reproduces by budding.

Ziehl-Neelsen stain One of the most widely used methods of acid-fast staining; it is commonly used during the microscopic examination of a smear of sputum that is suspected of containing *Mycobacterium tuberculosis*.

Zone of inhibition An area of no bacterial growth around an antimicrobial disc that indicates some sensitivity of the organism to the particular antimicrobial.

Zoonoses Diseases that can be transmitted between animals and humans.

Zygospores The spores that result from the conjugation of two isogametes, as occurs with certain fungi and algae.
